ABSTRACT

Background

Various approaches to physical rehabilitation may be used after stroke, and considerable controversy and debate surround the effectiveness of relative approaches. Some physiotherapists base their treatments on a single approach; others use a mixture of components from several different approaches.

Objectives

To determine whether physical rehabilitation approaches are effective in recovery of function and mobility in people with stroke, and to assess if any one physical rehabilitation approach is more effective than any other approach.

For the previous versions of this review, the objective was to explore the effect of 'physiotherapy treatment approaches' based on historical classifications of orthopaedic, neurophysiological or motor learning principles, or on a mixture of these treatment principles. For this update of the review, the objective was to explore the effects of approaches that incorporate individual treatment components, categorised as functional task training, musculoskeletal intervention (active), musculoskeletal intervention (passive), neurophysiological intervention, cardiopulmonary intervention, assistive device or modality.

In addition, we sought to explore the impact of time after stroke, geographical location of the study, dose of the intervention, provider of the intervention and treatment components included within an intervention.

Search methods

We searched the Cochrane Stroke Group Trials Register (last searched December 2012), the Cochrane Central Register of Controlled Trials (CENTRAL) (*The Cochrane Library* Issue 12, 2012), MEDLINE (1966 to December 2012), EMBASE (1980 to December 2012), AMED (1985 to December 2012) and CINAHL (1982 to December 2012). We searched reference lists and contacted experts and researchers who have an interest in stroke rehabilitation.

Selection criteria

Randomised controlled trials (RCTs) of physical rehabilitation approaches aimed at promoting the recovery of function or mobility in adult participants with a clinical diagnosis of stroke. Outcomes included measures of independence in activities of daily living (ADL), motor function, balance, gait velocity and length of stay. We included trials comparing physical rehabilitation approaches versus no treatment, usual care or attention control and those comparing different physical rehabilitation approaches.

Data collection and analysis

Two review authors independently categorised identified trials according to the selection criteria, documented their methodological quality and extracted the data.

Main results

We included a total of 96 studies (10,401 participants) in this review. More than half of the studies (50/96) were carried out in China. Generally the studies were heterogeneous, and many were poorly reported.

Physical rehabilitation was found to have a beneficial effect, as compared with no treatment, on functional recovery after stroke (27 studies, 3423 participants; standardised mean difference (SMD) 0.78, 95% confidence interval (CI) 0.58 to 0.97, for Independence in ADL scales), and this effect was noted to persist beyond the length of the intervention period (nine studies, 540 participants; SMD 0.58, 95% CI 0.11 to 1.04). Subgroup analysis revealed a significant difference based on dose of intervention (P value < 0.0001, for independence in ADL), indicating that a dose of 30 to 60 minutes per day delivered five to seven days per week is effective. This evidence principally arises from studies carried out in China. Subgroup analyses also suggest significant benefit associated with a shorter time since stroke (P value 0.003, for independence in ADL).

We found physical rehabilitation to be more effective than usual care or attention control in improving motor function (12 studies, 887 participants; SMD 0.37, 95% CI 0.20 to 0.55), balance (five studies, 246 participants; SMD 0.31, 95% CI 0.05 to 0.56) and gait velocity (14 studies, 1126 participants; SMD 0.46, 95% CI 0.32 to 0.60). Subgroup analysis demonstrated a significant difference based on dose of intervention (P value 0.02 for motor function), indicating that a dose of 30 to 60 minutes delivered five to seven days a week provides significant benefit. Subgroup analyses also suggest significant benefit associated with a shorter time since stroke (P value 0.05, for independence in ADL).

No one physical rehabilitation approach was more (or less) effective than any other approach in improving independence in ADL (eight studies, 491 participants; test for subgroup differences: P value 0.71) or motor function (nine studies, 546 participants; test for subgroup differences: P value 0.41). These findings are supported by subgroup analyses carried out for comparisons of intervention versus no treatment or usual care, which identified no significant effects of different treatment components or categories of interventions.

Authors' conclusions

Physical rehabilitation, comprising a selection of components from different approaches, is effective for recovery of function and mobility after stroke. Evidence related to dose of physical therapy is limited by substantial heterogeneity and does not support robust conclusions. No one approach to physical rehabilitation is any more (or less) effective in promoting recovery of function and mobility after stroke. Therefore, evidence indicates that physical rehabilitation should not be limited to compartmentalised, named approaches, but rather should comprise clearly defined, well-described, evidenced-based physical treatments, regardless of historical or philosophical origin.

PLAIN LANGUAGE SUMMARY

Physical rehabilitation approaches for recovery of function, balance and walking after stroke

Question

We wanted to know whether physical rehabilitation approaches are effective in recovery of function and mobility in people with stroke, and if any one physical rehabilitation approach is more effective than any other approach.

Background

Stroke can cause paralysis of some parts of the body and other difficulties with various physical functions. Physical rehabilitation is an important part of rehabilitation for people who have had a stroke. Over the years, various approaches to physical rehabilitation

have been developed, according to different ideas about how people recover after a stroke. Often physiotherapists will follow one particular approach, to the exclusion of others, but this practice is generally based on personal preference rather than scientific rationale. Considerable debate continues among physiotherapists about the relative benefits of different approaches; therefore it is important to bring together the research evidence and highlight what best practice ought to be in selecting these different approaches.

Study characteristics

We identified 96 studies, up to December 2012, for inclusion in the review. These studies, involving 10,401 stroke survivors, investigated physical rehabilitation approaches aimed at promoting recovery of function or mobility in adult participants with a clinical diagnosis of stroke compared with no treatment, usual care or attention control or in comparisons of different physical rehabilitation approaches. The average number of participants in each study was 105: most studies (93%) included fewer than 200 participants, one study had more than 1000 participants, six had between 250 and 100 participants and 10 had 20 or fewer participants. Outcomes included measures of independence in activities of daily living (ADL), motor function (functional movement), balance, walking speed and length of stay. More than half of the studies (50/96) were carried out in China. These studies showed many differences in relation to the type of stroke and how severe it was, as well as differences in treatment, which varied according to both treatment type and duration.

Key results

This review brings together evidence confirming that physical rehabilitation (often delivered by a physiotherapist, physical therapist or rehabilitation therapist) can improve function, balance and walking after stroke. It appears to be most beneficial when the therapist selects a mixture of different treatments for an individual patient from a wide range of available treatments.

We were able to combine the results from 27 studies (3243 stroke survivors) that compared physical rehabilitation versus no treatment. Twenty-five of these 27 studies were carried out in China. Results showed that physical rehabilitation improves functional recovery, and that this improvement may last long-term. When we looked at studies that compared additional physical rehabilitation versus usual care or a control intervention, we found evidence to show that the additional physical treatment improved motor function (12 studies, 887 stroke survivors), standing balance (five studies, 246 stroke survivors) and walking speed (14 studies, 1126 stroke survivors). Very limited evidence suggests that, for comparisons of physical rehabilitation versus no treatment and versus usual care, treatment that appeared to be effective was given between 30 and 60 minutes per day, five to seven days per week, but further research is needed to confirm this. We also found evidence of greater benefit associated with a shorter time since stroke, but again further research is needed to confirm this.

We found evidence showing that no one physical rehabilitation approach was more effective than any other approach. This finding means that physiotherapists should choose each individual patient's treatment according to the evidence available for that specific treatment, and should not limit their practice to a single 'named' approach.

Quality of the evidence

It was difficult for us to judge the quality of evidence because we found poor, incomplete or brief reporting of information. We determined that less than 50% of the studies were of good quality, and for most studies, the quality of the evidence was unclear from the information provided.

Physiotherapy intervention compared with no treatment for recovery after stroke

Patient or population: adults with stroke Intervention: physiotherapy interventions Comparison: no treatment

Outcomes	Standardised mean dif- ference (95% CI)	No. of participants (studies)	Quality of the evidence (GRADE)	Comments
Independence in ADL scales Immediate outcome	0.78 (0.58 to 0.97)	27 studies 3423 participants	⊕⊕⊕⊖ moderate	Substantial heterogeneity in results. Most studies are at high or unclear risk of bias. GRADE Working Group grades of evidence.

High quality: Further research is very unlikely to change our confidence in the estimate of effect.

Moderate quality: Further research is likely to have an important impact on our confidence in the estimate of effect and may change the estimate.

Low quality: Further research is very likely to have an important impact on our confidence in the estimate of effect and is likely to change the estimate.

Very low quality: We are very uncertain about the estimate.

BACKGROUND

Description of the condition

Stroke is a leading cause of death and disability in many Western nations. In Australia, the UK and the USA, it is within the top 10 causes of long-term physical disability (Fisher 2013; Mathers 2006; Ovbiagele 2011). The most common and widely recognised impairment caused by stroke is motor impairment, which can be regarded as loss or limitation of function in muscle control or movement or limitation in mobility (Wade 1992a). Motor impairment after stroke typically affects the control of movement of the face, arm and leg on one side of the body (Warlow 2008) and is seen in about 80% of patients. Almost two-thirds of stroke survivors have initial mobility deficits (Jorgensen 1995; Shaughnessy 2005), and six months after a stroke, more than 30% of survivors still cannot walk independently (Jorgensen 1995; Mayo 2002; Patel 2000). Therefore, much of the focus of stroke rehabilitation, in particular, the work of physiotherapists (also known as physical therapists or rehabilitation therapists), is focused on recovery of physical independence and functional ability during activities of daily living; commonly the ultimate goal of therapy is to improve the function of walking and recovery of balance and movement (Langhorne 2009).

Description of the intervention

Various approaches to physical rehabilitation can be used after stroke, and considerable controversy and debate about the relative effectiveness of these approaches are ongoing (Carlisle 2010; Kollen 2009). Descriptions of these approaches are best considered within a historical context.

Before the 1940s, physical rehabilitation approaches primarily consisted of corrective exercises based on orthopaedic principles

related to contraction and relaxation of muscles, with emphasis placed on regaining function by compensating with the unaffected limbs (Ashburn 1995; Partridge 1996). In the 1950s and 1960s, techniques based on available neurophysiological knowledge were developed to enhance recovery of the paretic side. These new approaches included the methods of Bobath (Bobath 1990; Davies 1985), Brunnström (Brunnström 1970) and Rood (Goff 1969), as well as the proprioceptive neuromuscular facilitation approach (Knott 1968; Voss 1985). In the 1980s, the potential importance of neuropsychology and motor learning was highlighted (Anderson 1986; Turnbull 1982) and the motor learning, or relearning, approach was proposed (Carr 1982). This suggested that active practice of context-specific motor tasks with appropriate feedback would promote learning and motor recovery (Carr 1980; Carr 1982; Carr 1987a; Carr 1987b; Carr 1989; Carr 1990; Carr 1998). The practical application of these approaches appeared to result in substantial differences in patient treatment. Approaches based on neurophysiological principles seemingly involved the physiotherapist moving the patient through patterns of movement, with the therapist acting as problem solver and decision maker and the patient being a relatively passive recipient (Lennon 1996). In direct contrast, motor learning approaches stressed the importance of active involvement by the patient (Carr 1982), and orthopaedic approaches emphasised muscle strengthening techniques and compensation with the non-paretic side.

Since the 1980s, the need to base neurological physiotherapy on scientific research in relevant areas such as medical science, neuroscience, exercise physiology and biomechanics, and to test the outcomes of physical interventions to develop evidence-based physiotherapy has been increasingly emphasised. However, anecdotal evidence and the results of questionnaire-based studies suggest that, traditionally, many physiotherapists continued to base their clinical practice around a 'named' treatment approach. From the 1990s, the Bobath approach, based on neurophysiological prin-

ciples, came to be recognised as the most widely used method in Sweden (Nilsson 1992), Australia (Carr 1994a) and the UK (Davidson 2000; Lennon 2001; Sackley 1996). As a consequence, since this time, physiotherapists have often sought evidence related to these 'named' approaches to the physical rehabilitation of stroke patients.

In some parts of the world, clear preferences for one 'named' approach have prevailed; however in others, physical rehabilitation approaches for stroke have developed with greater eclecticism, resulting in geographical preferences for mixing particular approaches, or components from different approaches, as well as preferences for single 'named' approaches. For example, in China, where stroke rehabilitation is not yet considered standard care (Zhang 2013), standard 'approaches' to rehabilitation have been proposed, including 'standardised tertiary rehabilitation' (Hu 2007 isch; Hu 2007a; Jiang 2006; Research Group 2007; Zhang 2004) and 'standardised three-phase rehabilitation' (Bai 2008; Fan 2006; Zhu 2004b). These approaches arguably appear to draw on the full range of treatment interventions available from all orthopaedic, neurophysiological and motor learning approaches described in Western literature, while incorporating traditional Chinese therapies such as acupuncture (Zhang 2013; Zhuang 2012). More recently, calls asking physiotherapists to cease using named approaches and to stop selecting treatments based on historical perspectives have increased. Physiotherapists have been urged to refrain from using compartmentalised, named approaches and to select clearly defined and described techniques and task-specific treatments, regardless of their historical or philosophical origin (Kollen 2009; Langhammer 2012; Mayston 2000; Pomeroy 2005). Although a move away from named approaches in preference of more evidence-based approaches has been deliberately implemented in some countries, such as the Netherlands (Kollen 2009; van Peppen 2004), heated debate continues about the evidence for doing this (Carlisle 2010), and some physiotherapists around the world continue to exhibit preferences for particular named approaches (Khan 2012; Tyson 2009a; Tyson 2009b).

Why it is important to do this review

Continued controversy and debate about the relative effectiveness of physical rehabilitation approaches and evidence of clear preferences for particular named approaches in some parts of the world, despite increasing calls for this to change, justify the importance of this review.

Why it is important to address limitations within previous versions of this review

The original versions of this review classified approaches to physiotherapy on the basis of historical principles described in the literature; however we classified interventions as neurophysiological, motor learning, orthopaedic or mixed, according to the descriptor or name of the intervention provided by trialists (Pollock 2007). Table 1 displays the criteria that we used in classifying neurophysiological and motor learning approaches (NB: We are not using these criteria in this updated review.). However, the 2007 version of the review (Pollock 2007) identified several limitations associated with this method of classification.

1. This classification was based on Western approaches and descriptions of physiotherapy and did not incorporate physical therapy delivered across the whole world. In Pollock 2007, we identified a large number (26) of non-English language (23 Chinese) trials (and classified them as 'studies awaiting assessment'). We stated: "The information currently available from the majority of the Chinese trials awaiting assessment suggests that it is unlikely that the interventions studied in these trials will fit into the western categorisations and classifications of physiotherapy treatment approaches developed for this review. Prior to the next update of this review, the authors intend to seek advice and write additional inclusion and exclusion criteria to deal with the non-western approaches to physiotherapy for stroke".

2. The 'mixed' approach category within the review could potentially incorporate a large number of heterogeneous interventions that may not be meaningful to combine. Pollock 2007 stated: "A limitation of combining all mixed approaches is that this category potentially amalgamates any number of possible combinations of other approaches and techniques".

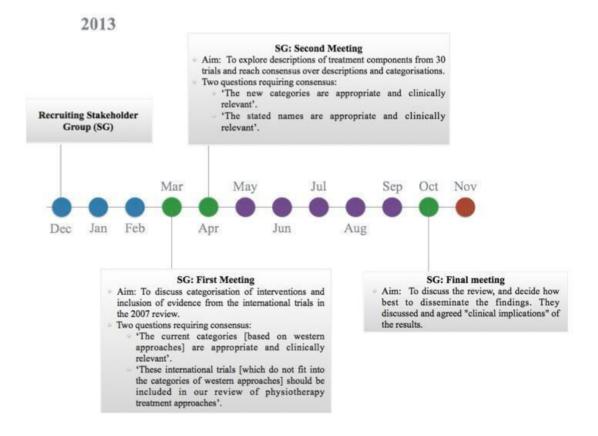

3. We found difficulties in determining the classifications of motor learning and mixed approaches for some studies. Pollock 2007 stated: "difficulty was experienced in distinguishing between a mixed approach (not a mixture of two different approaches, such as Stern 1970 mixing orthopaedic and neurophysiological approaches, but an unclassified mix [where the interventions were not easily classified into a 'named' approach]) and a motor learning approach. The mixed, intensive and focused approach investigated by Richards 1993 and the problem-solving approach investigated by Green 2002 and Wade 1992 had stated philosophies very similar to those of motor learning approaches. However, the described techniques and the supporting references led the reviewers to classify these interventions as mixed. This highlights a key problem with the classification of the motor learning approach. Although a motor relearning programme has been described by Carr and Shepherd (Carr 1982; Carr 1987b), these authors primarily advocate an approach based on related research in relevant areas such as medical science, neuroscience, exercise physiology and biomechanics. Such an approach is arguably one of research-based practice, rather than being based on one specific philosophy".

It was therefore essential to plan solutions and strategies to address these limitations before this update of the review was conducted.

Consensus methods to inform update of this review

To address the identified limitations within previous versions of this review, before this update we convened a stakeholder group comprising 13 purposively selected people: three stroke survivors, one carer and nine physiotherapists. Members of this group are listed and acknowledged in the Acknowledgements section. We used formal group consensus methods to reach consensus decisions around review aims and methods, while focusing on clinical relevance, as such methods are recognised to be advantageous when subjective judgements need to be organised (Nair 2011). The consensus methods were based on nominal group techniques, as this method enables the pooling of decisions and judgements from a group of informed experts, leading to votes on a range of options until ultimately group consensus is reached (Sinha 2008; Stapleton 2010). The review authors attended the stakeholder group meetings and contributed to discussions; however we did not participate in the voting process. This approach was taken to ensure that the results of the voting reflected the views of stroke survivors, carers and physiotherapists and were not biased by the opinions of the review authors. The process of stakeholder group involvement is outlined in Figure 1.

Figure 1. The figure summarises the process undertaken by the stakeholder group, which met on three occasions (green circles). The nominal group technique was used to achieve all decisions. The blue circles represent the 'preparation phase,' which included drafting role descriptors for the SG; obtaining local
 University ethics and recruiting the SG and data extraction exercise of the sample of Chinese studies (n = 10) that had previously been identified in the 2007 version of this review. Purple circles represent the months dedicated to undertaking the systematic review.

The stakeholder group specifically discussed the categorisation of interventions and inclusion of evidence from the international trials listed as awaiting assessment in Pollock 2007, which led to voting on two key statements.

1. "The current categories (based on western approaches) are appropriate and clinically relevant".

2. "These international trials (which do not fit into the categories of western approaches) should be included in our review of physiotherapy treatment approaches".

We determined the proportion agreeing with each statement. We audio-recorded and transcribed verbatim the consensus decision meetings. We coded and analysed qualitative data using NVivo software: 84% of group members disagreed with statement 1, and 100% agreed with statement 2. Two key themes and several subthemes emerged from the transcribed data. Key themes were that (1) current categories of rehabilitation approaches should be amended to enable inclusion of all international evidence and (2) current physiotherapy taxonomies have limitations and concerns that have been raised surrounding their relevance to clinical practice in the UK.

Discussion amongst stakeholder group members led to the generation of, and agreement on, a proposal that the optimal way of classifying the 'approaches' for this review consisted of using systematic categorisation of the treatment components described in relation to interventions. This discussion followed a presentation of treatment components described in a sample of 10 Chinese trials that had been listed as 'awaiting assessment' in Pollock 2007 (Chen 2004; Chu 2003; Gong 2003; Huang 2003; Pan 2004; Pang 2003; Xie 2003; Xu 2003a; Zhang 1998; Zhu 2001). On the suggestion of the stakeholder group, to further explore the range of treatment components and reach agreement on definitions of these components, we systematically extracted descriptions of physical rehabilitation approaches from the 20 trials included in Pollock 2007 (Dean 1997; Dean 2000; Duncan 1998; Duncan 2003; Gelber 1995; Green 2002; Hesse 1998; Howe 2005; Langhammer 2000; Lincoln 2003; McClellan 2004; Mudie 2002; Ozdemir 2001; Pollock 1998; Richards 1993; Salbach 2004; Stern 1970; Wade 1992; Wang 2005; Wellmon 1997). The stakeholder group then explored the descriptions of treatment components from these 30 trials. The aim was to include a variety of types and descriptions of physical rehabilitation approaches to allow examination of whether a range of treatment components could be identified and consensus over descriptions and categorisations; this was designed as an exploration, rather than as a comprehensive aggregation. The stakeholder group debated the treatment components described within these trials of physical rehabilitation approaches, reached consensus on key components, agreed on descriptions of these components and determined categorisation for synthesis of evidence within this update of the Cochrane review.

The stakeholder group identified and defined 27 treatment components based on the interventions described within the 30 explored trials. These were grouped into seven categories: functional task training, musculoskeletal intervention (active), musculoskeletal intervention (passive), neurophysiological intervention, cardiopulmonary intervention, assistive device and modality. These categories were informed by the taxonomy described by DeJong 2004. One hundred per cent of the stakeholder group agreed with these treatment component descriptions and categories. The agreed upon categories, treatment components and definitions are listed in Table 2.

OBJECTIVES

To determine whether physical rehabilitation approaches are effective in recovery of function and mobility in people with stroke, and to assess if any one physical rehabilitation approach is more effective than any other approach.

For the Pollock 2007 version of the review and earlier versions, the objective was to explore the effect of 'physiotherapy treatment approaches' based on historical classifications of orthopaedic, neurophysiological or motor learning principles, or on a mixture of these treatment principles. For this update of the review, the objective was to explore the effects of approaches that incorporate treatment components from each of the categories listed in Table 2, Individual treatment components were categorised as functional task training, musculoskeletal intervention (active), musculoskeletal intervention, cardiopulmonary intervention, assistive device or modality.

In addition, we sought to explore the impact of time after stroke, geographical location of the study, dose of the intervention, provider of the intervention and treatment components included within an intervention.

METHODS

Criteria for considering studies for this review

Types of studies

We included controlled trials if the participants were randomly assigned to one of two or more treatment groups. Random assignment gives each participant entering the trial the same, predetermined, chance of receiving each of the possible treatments (e.g. by using sequentially numbered opaque sealed envelopes or computer-generated random numbers). We included trials with or without blinding of participants, physiotherapists and assessors. We excluded trials with quasi-random assignment, thereby excluding a number of trials that had been included in previous versions of this review (Hesse 1998; Ozdemir 2001; Stern 1970).

Types of participants

We included trials enrolling adult participants (over 18 years of age) with a clinical diagnosis of stroke (World Health Organization definition; Hatano 1976), which could be ischaemic or haemorrhagic in origin (confirmation of the clinical diagnosis by imaging was not compulsory).

Types of interventions

We included physical rehabilitation approaches that were aimed at promoting recovery of postural control (balance during maintenance of a posture, restoration of a posture or movement between postures) and lower limb function (including gait), as well as interventions that had a more generalised stated aim, such as improving functional ability. We excluded rehabilitation approaches that were primarily aimed at promoting recovery of upper limb movement or upper limb function.

Types of outcome measures

Primary outcomes

We defined primary outcomes as measures of disability (activity limitations; WHO 2002) and prestated relevant measures as follows.

1. Independence in activities of daily living (ADL)* scales. These include Barthel Activities of Daily Living Index (Mahoney 1965), Functional Independence Measure (FIM) (Keith 1987), Modified Rankin Scale (van Swieten 1988), Katz Index of Activities of Daily Living (Katz 1970) and Rehabilitation Activities Profile (van Bennekom 1995).

2. Motor function* scales. These include Motor Assessment Scale (MAS) (Carr 1985), Fugl-Meyer Assessment (lower limb section) (Fugl-Meyer 1975), Rivermead Mobility Index (Forlander 1999) and Rivermead Motor Assessment (Lincoln 1979).

Secondary outcomes

- 1. Balance (Berg Balance Scale) (Berg 1989; Berg 1992).
- 2. Gait velocity.
- 3. Length of stay.

We were interested in outcomes that were assessed both immediately after the end of an intervention period ('immediate outcome') and at a follow-up period ('persisting outcomes'). *See Differences between protocol and review.

Search methods for identification of studies

See the 'Specialized register' section in the Cochrane Stroke Group module. We searched for trials in all languages and arranged translation of relevant papers published in languages other than English.

Electronic searches

We searched the Cochrane Stroke Group Trials Register, which was last searched in December 2012, the Cochrane Central Register of Controlled Trials (CENTRAL) (*The Cochrane Library* Issue 12, 2012), MEDLINE (Ovid) (1966 to December 2012) (Appendix 1), EMBASE (Ovid) (1980 to December 2012) (Appendix 2), AMED (Ovid) (1985 to December 2012) (Appendix 3) and CINAHL (EBSCO) (1982 to December 2012) (Appendix 4). With the help of the Cochrane Stroke Group Trials Search Co-ordinator, we developed comprehensive search strategies for MED-LINE (adapted for CENTRAL), EMBASE, AMED and CINAHL using controlled vocabulary and free text terms. We updated the search strategies for this review to incorporate new vocabulary terms.

Searching other resources

We handsearched the reference lists of all trials found using the above search methods.

For the original version of this review, we contacted relevant experts from the Physiotherapy Researchers Register, held by the Chartered Society of Physiotherapy, and asked whether they knew of any additional, unpublished or ongoing trials of rehabilitation approaches for stroke. We also placed a request on the PHYSIO email discussion list asking the list members (who originate from approximately 35 countries) if they knew of any unpublished or ongoing trials of rehabilitation approaches for stroke. We identified no relevant additional, unpublished or ongoing trials through contact with experts from the Physiotherapy Researchers Register and received no relevant responses from the PHYSIO email discussion list.

For future updates of this review, we plan to expand search resources to include the REHABDATA Database (www.naric.com/? q=en/REHABDATA), Wangfangdata, a database of Chinese studies (www.wanfangdata.com/) and the major ongoing trials and research registers.

Data collection and analysis

Selection of studies

One review author (AP or PC or PLC) read the titles of the identified references and eliminated obviously irrelevant studies. We obtained the abstracts for the remaining studies and then, based on the inclusion criteria (types of studies, types of participants, aims of interventions, outcome measures), two review authors (AP, PC, PLC or GB) independently ranked these as relevant, irrelevant or unsure. We discussed abstracts written in Chinese, with one review author (PLC) translating relevant sections and verbally providing information to other review authors in English (AP, PC).

We excluded studies ranked as irrelevant by all review authors and obtained the full text of all remaining studies.

We considered the full texts of studies ranked as relevant or unsure and resolved disagreements through discussion between review authors. We included all trials that were assessed to investigate different physical rehabilitation approaches and excluded all trials of single specific treatments. Single specific treatments included biofeedback, functional electrical stimulation, treadmill walking, acupuncture, ankle-foot orthoses, continuous passive movement and transcutaneous electrical nerve stimulation. Some of these single specific treatments have been the subject of other Cochrane reviews (e.g. Moseley 2005; Pomeroy 2006).

Data extraction and management

Two review authors independently performed the data extraction, and we contacted study authors to request missing data when possible (AP, GB, PC, PLC). The data extracted included the following (when possible): trial setting (e.g. hospital, community); details of participants (e.g. age, gender, side of hemiplegia, stroke classification, co-morbid conditions, premorbid disability); inclusion and exclusion criteria; and all assessed outcomes. The review authors resolved disagreements by discussion and contacted study authors for clarification when necessary. For papers published in Chinese, one review author (PLC) performed data extraction and translated relevant sections of text, which a second review author (AP, PC) checked.

Two review authors (AP, PLC) independently scrutinised the descriptions of interventions provided in each included trial and determined the treatment components included within each trial, based on the agreed upon definitions of treatment components (Table 2). Descriptions of interventions that were available only in Chinese were translated (and components classified) by one review author (PLC) and the translated descriptions used for the classification of components by a second review author (AP). We resolved disagreements through discussion and obtained further information from trialists when necessary (and possible).

Assessment of risk of bias in included studies

Two review authors independently documented the methodological quality of the studies, recording the following quality criteria: randomisation (allocation concealment); baseline comparison of groups; blinding of recipients and providers of care to treatment group/study aims; blinding of outcome assessor; possibility of contamination/co-intervention by the therapists providing the intervention; completeness of follow-up and other potential confounders (AP, GB, PC, PLC). The review authors resolved disagreements by discussion and contacted study authors for clarification when necessary.

One review author (PLC) translated relevant extracts related to the methodological quality of studies written in Chinese and assessed their methodological quality. A second review author (AP) checked the documentation of methodological quality, based on the translated extracts.

Measures of treatment effect

We presented all analysed outcome measures as continuous data. We calculated standardised mean differences (SMDs) and 95% confidence intervals (CIs), using a random-effects model for all outcomes analysed, with the exception of length of stay, for which we calculated mean differences (MDs) and 95% CIs, as length of stay was reported in number of days by all studies.

Data synthesis

We changed the comparisons included in the review for this update, based on consensus decisions reached by the expert stakeholder group (see Background). In earlier versions of this review, the comparisons were structured around 'named' rehabilitation approaches, as reported in the included studies (e.g. Bobath, Motor Relearning Programme). For this update, we planned to carry out comparisons of physical rehabilitation approaches that included treatment components within the categories of functional task training, musculoskeletal intervention (active), musculoskeletal intervention (passive), neurophysiological intervention, cardiopulmonary intervention, assistive device and modality (see Table 2). Categories were based on the treatment components described within each included study. We planned to compare active interventions with (1) no treatment, (2) usual care or control and (3) another active intervention.

Subgroup analysis and investigation of heterogeneity

We planned to carry out subgroup analysis to explore the effects of time post stroke of participants, geographical location of the study, dose of the intervention and the profession of the person who delivered the intervention (i.e. physiotherapist, nurse, therapy assistant). We also planned to explore the effects of including different individual treatment components.

Sensitivity analysis

We planned to carry out sensitivity analyses to explore the effects of methodological quality, based on assessment of risk of bias.

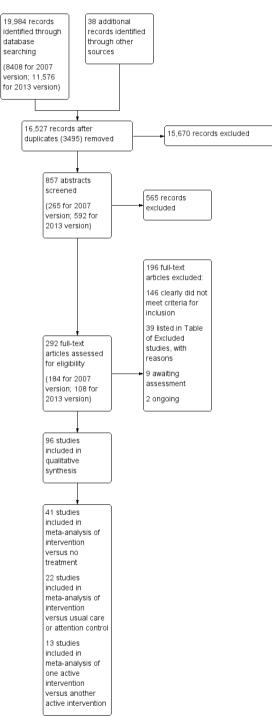

RESULTS

Description of studies

Results of the search

Results of the search are displayed in Figure 2.

2007 version

For the 2007 version of this review, we identified 8408 potentially relevant trials by electronic searching; we considered 184 full papers and included 20 trials (1087 participants) (Dean 1997; Dean 2000; Duncan 1998; Duncan 2003; Gelber 1995; Green 2002; Hesse 1998; Howe 2005; Langhammer 2000; Lincoln 2003; McClellan 2004; Mudie 2002; Ozdemir 2001; Pollock 1998; Richards 1993; Salbach 2004; Stern 1970; Wade 1992; Wang 2005; Wellmon 1997).

2013 update

For this update of this review, we identified 11,576 (8120 with duplicates removed) potentially relevant studies. We considered 108 full papers and included 96 trials (10,401 participants) (including the 20 within the 2007 version).

We identified two relevant ongoing studies (see Characteristics of ongoing studies), and we had insufficient information to reach decisions on nine studies (see Characteristics of studies awaiting classification). We excluded three studies that had been included in the 2007 version, as they used quasi-random assignment (Hesse 1998; Ozdemir 2001; Stern 1970) (see Figure 2).

Included studies

We included a total of 96 studies (10,401 participants) in this review. Two studies divided participants according to type of stroke (ischaemic or haemorrhagic) before randomisation and presented results within these two groups: These have been entered as four separate studies: Hu 2007 haem and Hu 2007 isch, and Zhu 2007 isch and Zhu 2007 haem. The data for Fang 2004 were presented in two groups, according to the age of participants, so these data have also been presented separately (Fang 2004 old and Fang 2004 young). Thus a total of 99 studies are referenced as included studies in this review. Details of these 99 studies are provided in Characteristics of included studies.

The mean number of participants was 105 (SD 151). Ninetytwo of the 99 studies included fewer than 200 participants. One study had more than 1000 participants (Zhang 2004; 1078 participants); and six had between 250 and 100 participants (Bai 2008, 364; Behrman 2011, 408; Hu 2007 haem, 352; Hu 2007 isch, 965; Kwakkel 2008, 250; Zhao 2003, 300). Ten studies included 20 or fewer participants (Aksu 2001, 20; Allison 2007, 17; Bale 2008, 18; Carlson 2006, 11; Dean 1997, 20; Dean 2000, 12; Dean 2007, 12; Duncan 1998, 20; Kim 2012, 20; Stephenson 2004, 18).

Intervention categories

Details of the categories and treatment components of the active interventions are provided in Table 3. Of the 99 studies, 23 investigated two active interventions (19 of which directly compared two active interventions; and four of which had three intervention groups, of which two were active interventions). Thus a total of 122 active interventions were studied (99 included studies plus 23 studies with a second active intervention).

The most common intervention category was functional task training, with 101 of the 122 active interventions categorised as including treatment components from functional task training.

1. Of these 101 interventions, 20 included only functional task training components.

2. Of these 101 interventions, 26 included functional task training plus one other category. The second category was neurophysiological for six interventions; modality for two interventions; musculoskeletal (passive) for nine interventions; musculoskeletal (active) for eight interventions and cardiopulmonary for one intervention.

3. Of these 101 interventions, 32 included functional task training plus two other categories. The other categories included neurophysiological for 11 interventions; musculoskeletal (active) and musculoskeletal (passive) for 13 interventions; musculoskeletal (active or passive) plus other categories for seven interventions; and cardiopulmonary and assistive devices for one intervention.

4. Of these 101 interventions, 19 included functional task training plus three other categories. The other categories were neurophysiological plus musculoskeletal (active) plus musculoskeletal (passive) for nine interventions; neurophysiological plus other categories for eight interventions; and musculoskeletal (active) plus musculoskeletal (passive) plus another category for two interventions.

5. Of these 101 interventions, four included functional task training plus four other categories. The other categories were modalities, musculoskeletal (passive), musculoskeletal (active) and neurophysiological for three interventions; assistive devices, musculoskeletal (passive), musculoskeletal (active) and neurophysiological for one intervention; and modalities, musculoskeletal (passive), musculoskeletal (active) and assistive devices for one intervention.

Of the remaining 21 of the 122 interventions, most (17 interventions) included components from the neurophysiological category.

1. Of these 17 interventions, only 12 implemented neurophysiological treatment components.

2. Of these 17 interventions, five implemented neurophysiological plus a combination of musculoskeletal (active), musculoskeletal (passive) and/or modalities. Of the remaining four interventions:

1. one included musculoskeletal (active) and musculoskeletal (passive) components;

2. two included musculoskeletal (passive) components only; and

3. one included a modality only (this modality was acupuncture; Zhuang 2012).

Comparison groups

The studies included in this review compare an active intervention with:

1. no treatment (55 studies: see Table 4 for further details);

2. usual care (19 studies) or attention control (11 studies) (see Table 5 for further details); or

3. another active intervention (23 studies: see Table 6 for further details).

A total of 108 comparisons were performed, as five of the 99 studies contributed data on more than one comparison. Four studies contributed data on three comparisons: Cooke 2006, Mudie 2002 and Richards 1993 each compared two active treatments with usual care, and Baer 2007 compared two active treatments with no treatment. Of the 99 studies, one contributed data on two comparisons: Kwakkel 2002 compared an active intervention with both an attention control group and a no treatment group.

Study location

Table 7 lists the geographical locations of the included studies. Of the 99 included studies, 97 recruited participants from one country or continent, and two studies recruited participants from two countries or continents (Brock 2005: Australia and Europe; Thaut 2007: North America and Europe). A total of 54 studies were carried out in China; 17 in Europe; 10 in North America and Canada; seven in Australia and New Zealand; eight in Asia, excluding China and one in South America.

The mean study size was greater in studies carried out in China (mean 138, SD 189 participants) than in other parts of the world (Europe: mean 76, SD 60; North America and Canada: mean 74, SD 122; Australia and New Zealand: mean 48, SD 48; Asia, excluding China: mean 46, SD 30).

The settings for recruitment of participants and for administration of the intervention are summarised in Table 7.

Table 8 illustrates the types of control interventions included in studies in different geographical locations. Of the 54 studies, 44 including a no-treatment comparison were carried out in China.

Study participants

Table 9 displays details of the participants included in the studies. In 38 of the 99 studies, the time since stroke was 30 days or less (Allison 2007; Bai 2008; Chen 2004; Chen 2010; Dean 2007; Deng 2011; Fan 2006; Gelber 1995; Hou 2006; Howe 2005; Hu 2007 haem; Hu 2007 isch; Huang 2003; Jiang 2006; Jing 2006; Li 2005; Liao 2006; Lincoln 2003; Liu 2003; Ni 1997; Qian 2004; Qian 2005; Richards 1993; Thaut 2007; Torres-Arreola 2009; Wang 2005; Wang 2006; Wu 2006; Xiao 2003; Xie 2003; Xu 2003a; Xu 2003b; Xu 2004; Yan 2002; Zhu 2001; Zhu 2004b; Zhu 2007 isch; Zhu 2007 haem).

In 12 of the 99 studies, the time since stroke was 90 days or less (Bale 2008; Cooke 2006; Duncan 1998; Ge 2003; Mudie 2002;

Pollock 1998; Verheyden 2006; Verma 2011; Wang 2004b; Wei 1998; Zhu 2006; Zhuang 2012).

In eight of the 99 studies, the time since stroke was six months or less (Blennerhassett 2004; Brock 2005; Chan 2006; Duncan 2003; Holmgren 2006; Kwakkel 2002; Kwakkel 2008; Wellmon 1997).

In three of the 99 studies, the time since stroke was 12 months or less (McClellan 2004; Salbach 2004; Yelnik 2008).

In 10 of the 99 studies, the time since stroke was longer than 12 months (Baer 2007; Chen 2006; Dean 1997; Dean 2000; Dean 2006; Hui-Chan 2009; Kim 2011; Kim 2012; Mudge 2009; Wade 1992).

The time since stroke was not stated in 28 of the 99 studies (Aksu 2001; Behrman 2011; Carlson 2006; Chu 2003; Fang 2003; Fang 2004 old; Fang 2004 young; Green 2002; Langhammer 2000; Langhammer 2007; Lennon 2006; Li 1999; Li 2003; Pan 2004; Pang 2003; Pang 2006; Shin 2011; Stephenson 2004; Tang 2009; Wang 2004a; Xie 2005; Xu 1999; Xue 2006; Yin 2003a; Zhang 1998; Zhang 2004; Zhao 2002; Zhao 2003).

Dose of intervention

The duration of the intervention period was 28 days or less in 35 studies (Allison 2007; Baer 2007; Bale 2008; Blennerhassett 2004; Brock 2005; Carlson 2006; Chen 2010; Dean 1997; Dean 2000; Dean 2007; Fang 2003; Fang 2004 old; Fang 2004 young; Howe 2005; Hui-Chan 2009; Kim 2012; Lennon 2006; Liao 2006; Liu 2003; Mudge 2009; Pang 2003; Pollock 1998; Shin 2011; Stephenson 2004; Thaut 2007; Verma 2011; Wang 2004b; Wang 2005; Wellmon 1997; Xiao 2003; Xu 2003a; Xu 2003b; Yelnik 2008; Zhao 2003; Zhuang 2012); 12 weeks or less in 24 studies (Chan 2006; Chen 2004; Chen 2006; Cooke 2006; Deng 2011; Duncan 1998; Holmgren 2006; Huang 2003; Kim 2011; Kwakkel 2008; Li 1999; McClellan 2004; Mudie 2002; Ni 1997; Salbach 2004; Tang 2009; Verheyden 2006; Wang 2004a; Wei 1998; Xu 1999; Xu 2004; Xue 2006; Yan 2002; Zhao 2002); between 12 weeks and six months in 16 studies (Bai 2008; Behrman 2011; Duncan 2003; Green 2002; Hou 2006; Hu 2007 haem; Hu 2007 isch; Jiang 2006; Kwakkel 2002; Pang 2006; Torres-Arreola 2009; Wang 2006; Wu 2006; Xie 2005; Zhang 2004; Zhu 2004b) and over six months in three studies (Chu 2003; Dean 2006; Langhammer 2007). The intervention period was unclear in 21 of the 99 studies (Aksu 2001; Fan 2006; Ge 2003; Gelber 1995; Jing 2006; Langhammer 2000; Li 2003; Li 2005; Lincoln 2003; Pan 2004; Qian 2004; Qian 2005; Richards 1993; Wade 1992; Xie 2003; Yin 2003a; Zhang 1998; Zhu 2001; Zhu 2006; Zhu 2007 isch; Zhu 2007 haem).

The frequency of intervention was more than once per day in 22 studies (Blennerhassett 2004; Carlson 2006; Fan 2006; Hou 2006; Jiang 2006; Kim 2012; Li 1999; Liu 2003; McClellan 2004; Ni 1997; Pan 2004; Pang 2003; Wang 2004a; Wellmon 1997; Xie 2003; Xie 2005; Xu 1999; Xue 2006; Yan 2002; Zhu 2004b; Zhu 2007 isch; Zhu 2007 haem); once per day for five to seven

days per week for 30 to 60 minutes in 33 studies (Allison 2007; Bai 2008; Bale 2008; Chu 2003; Dean 1997; Dean 2007; Deng 2011; Fang 2003; Fang 2004 old; Fang 2004 young; Holmgren 2006; Hui-Chan 2009; Kim 2011; Kwakkel 2002; Langhammer 2000; Lennon 2006; Li 2005; Liao 2006; Mudie 2002; Pang 2006; Pollock 1998; Shin 2011; Thaut 2007; Verma 2011; Wang 2004b; Wang 2005; Wei 1998; Xu 2004; Yelnik 2008; Zhao 2002; Zhu 2001; Zhu 2006; Zhuang 2012); three to four times per week in 12 studies (Brock 2005; Chan 2006; Cooke 2006; Dean 2000; Dean 2006; Duncan 1998; Duncan 2003; Mudge 2009; Salbach 2004; Stephenson 2004; Verheyden 2006; Xiao 2003); one to two times per week in two studies (Chen 2006; Kwakkel 2008) and less frequent than once per week in one study (Baer 2007). The frequency was unclear in 29 of the 99 studies (Aksu 2001; Behrman 2011; Chen 2004; Chen 2010; Ge 2003; Gelber 1995; Green 2002; Howe 2005; Hu 2007 haem; Hu 2007 isch; Huang 2003; Jing 2006; Langhammer 2007; Li 2003; Lincoln 2003; Qian 2004; Qian 2005; Richards 1993; Tang 2009; Torres-Arreola 2009; Wade 1992; Wang 2006; Wu 2006; Xu 2003a; Xu 2003b; Yin 2003a; Zhang 1998; Zhang 2004; Zhao 2003).

Table 10 displays the length and dose of intervention for those studies with Independence in ADL or motor function data in comparisons with no treatment, and Table 11 displays this information for studies with comparisons with usual care or attention control.

Definition of dose

We preplanned subgroup analyses to explore the effect of dose of intervention. We defined *dose* as including the components of (1) length of a single treatment session, (2) frequency of treatment sessions and (3) duration of the intervention period. However, because of the availability of data and the complexities associated with variations in these three components, our subgroup analyses of dose explored only the combination of (1) length of a single treatment session and (2) frequency of treatment sessions. We also performed additional sensitivity analyses to explore the impact of (3) duration of intervention period on subgroup analysis results.

Outcome measures for analysis

The included trials used a large number of heterogeneous outcome measures. The many diverse outcome measures recorded in the included studies made it impossible for review authors to analyse all of the documented data. Based on the prestated groupings of relevant outcomes and the availability of data from specific measures in the included trials, the review authors for the previous version of the review made the decision to concentrate data analysis on independence in ADL,* motor function,* balance, muscle strength, gait velocity and length of rehabilitation stay. For this update, we decided to remove the muscle strength outcome, as this outcome was rarely reported in the included studies. *Independence in ADL was called 'global dependency' and motor function was called 'functional independence in mobility' in previous versions of this review. See Differences between protocol and review.

Outcome measures were recorded at several different time points during and after the intervention period. For the analyses in the review, we classed 'immediate outcomes' as data that were recorded at the end of the treatment period or at the time point nearest to the end of the treatment period. If the intervention comprised a change in treatment throughout the whole of a participant's rehabilitation period, then data were recorded from the outcome measures noted at the time of discharge from rehabilitation or at the time point nearest to discharge. When studies also reported follow-up data, we included these as analysis of 'persisting outcome'. The time points at which data were recorded are clearly documented and stated for each trial in the Characteristics of included studies table and are summarised in Table 4, Table 5 and Table 6.

Of the 99 studies, 79 included outcome measures suitable for inclusion in an analysis of immediate outcomes, and 27 provided a follow-up outcome measure. Details of these outcome measures are provided below.

Studies included in meta-analysis

Independence in ADL scales

Forty-nine studies reported 'immediate outcome' data for a measure of independence in ADL. This was the Barthel Index (or modified Barthel Index) for 45 studies (Chen 2004; Chen 2006; Chen 2010; Chu 2003; Duncan 1998; Fang 2003; Fang 2004 old; Fang 2004 young; Green 2002; Holmgren 2006; Hou 2006; Huang 2003; Jing 2006; Langhammer 2007; Langhammer 2000; Lennon 2006; Li 1999; Li 2005; Lincoln 2003; Liu 2003; Mudie 2002; Pan 2004; Pang 2003; Pang 2006; Pollock 1998; Richards 1993; Thaut 2007; Torres-Arreola 2009; Wade 1992; Wu 2006; Xie 2003; Xu 1999; Xu 2003a; Xu 2003b; Xu 2004; Xue 2006; Yan 2002; Zhang 1998; Zhang 2004; Zhao 2002; Zhao 2003; Zhu 2006; Zhu 2007 isch; Zhu 2007 haem; Zhuang 2012) and the Functional Independence Measure (FIM) for four studies (Chan 2006; Gelber 1995; Ni 1997; Yelnik 2008).

Sixteen studies reported 'persisting outcome' data for a measure of independence in ADL. This was the Barthel Index (or modified Barthel Index) for 14 studies (Chen 2004; Fang 2003; Fang 2004 old; Fang 2004 young; Green 2002; Holmgren 2006; Hou 2006; Jing 2006; Lincoln 2003; Mudie 2002; Torres-Arreola 2009; Verma 2011; Wade 1992; Zhao 2003) and the FIM for two studies (Gelber 1995; Yelnik 2008). Verma 2011 reported a follow-up measurement but not an immediate measurement for the Barthel Index.

Standard deviations for Zhu 2007 isch and Zhu 2007 haem were estimated from the reported range, and data for Chen 2010 and

Zhao 2003 were estimated from categorical data; it was preplanned to explore the effect of including these studies.

Motor function scales

Fifty studies reported 'immediate outcome' data for a measure of motor function. This was the Rivermead Motor Assessment for six studies (Cooke 2006; Green 2002; Kwakkel 2008; Lincoln 2003; Mudge 2009; Wade 1992); the Motor Assessment Scale for six studies (Bale 2008; Langhammer 2007; Langhammer 2000; Lennon 2006; McClellan 2004; Wang 2005) and the Fugl-Meyer Assessment for 38 studies (Chen 2010; Chu 2003; Deng 2011; Duncan 1998; Duncan 2003; Fang 2003; Fang 2004 old; Fang 2004 young; Hu 2007 haem; Hu 2007 isch; Huang 2003; Jing 2006; Li 1999; Liao 2006; Liu 2003; Ni 1997; Pan 2004; Qian 2005; Richards 1993; Tang 2009; Thaut 2007; Wang 2004a; Wang 2004b; Wei 1998; Wu 2006; Xu 2003a; Xu 2003b; Xu 2004; Xue 2006; Yin 2003a; Zhang 1998; Zhang 2004; Zhao 2002; Zhu 2001; Zhu 2006; Zhu 2007 isch; Zhu 2007 haem; Zhuang 2012).

Twelve studies reported 'persisting outcome' data for a measure of motor function. This was the Rivermead Motor Assessment for six studies (Cooke 2006; Green 2002; Kwakkel 2008; Lincoln 2003; Mudge 2009; Wade 1992); the Motor Assessment Scale for one study (McClellan 2004); the Rivermead Mobility Index for one study (Cooke 2006) and the Fugl-Meyer Assessment for five studies (Fang 2003; Fang 2004 old; Fang 2004 young; Jing 2006; Zhao 2002).

Richards 1993 and Yin 2003a included two active treatment groups so are entered twice into analyses, with the control group data 'shared' as the comparison group for the two active interventions. Standard deviations for Green 2002, Mudge 2009, Zhu 2007 isch and Zhu 2007 haem were estimated from the reported range, it was preplanned to explore the effect of including these studies. Data from Jing 2006 were not included in analyses of one approach versus another, as both of the two treatment groups were assessed as including similar treatment components.

Balance (Berg Balance Scale)

Eleven studies reported 'immediate outcome' data for measures of balance (Brock 2005; Chan 2006; Duncan 1998; Duncan 2003; Holmgren 2006; Kim 2012; Richards 1993; Salbach 2004; Shin 2011; Wang 2005; Yelnik 2008). Holmgren 2006 and Yelnik 2008 also reported 'persisting outcome' data.

Richards 1993 included two active treatment groups so is entered twice into analyses, with the control group data 'shared' as the comparison group for the two active interventions. The data for Holmgren 2006 standard deviations were calculated from the reported confidence intervals.

Gait velocity

Twenty-three studies reported 'immediate outcome' data for measures of gait velocity (Bale 2008; Blennerhassett 2004; Brock 2005; Cooke 2006; Dean 1997; Dean 2000; Dean 2006; Dean 2007; Duncan 1998; Duncan 2003; Gelber 1995; Green 2002; Hui-Chan 2009; Kim 2012; Kwakkel 2008; Lincoln 2003; Richards 1993; Salbach 2004; Stephenson 2004; Thaut 2007; Verma 2011; Wade 1992; Yelnik 2008), and 13 studies reported 'persisting outcome' data (Blennerhassett 2004; Cooke 2006; Dean 2000; Dean 2007; Gelber 1995; Green 2002; Hui-Chan 2009; Kwakkel 2008; Lincoln 2003; Mudge 2009; Verma 2011; Wade 1992; Yelnik 2008).

Cooke 2006 and Richards 1993 included two active treatment groups so are entered twice into analyses, with the control group data 'shared' as the comparison group for the two active interventions. Standard deviations for Green 2002 and Mudge 2009 were estimated from the reported range, and data for Bale 2008 were estimated from categorical data; it was preplanned to explore the effect of including these studies.

Length of stay

Eight studies reported data relating to length of stay (Blennerhassett 2004; Gelber 1995; Holmgren 2006; Langhammer 2000; Langhammer 2007; Li 2003; Li 2005; Torres-Arreola 2009).

Studies included in meta-analysis comparisons

Intervention versus no treatment

Of the 54 studies included in this review that compared an active intervention with no treatment, 41 included data suitable for inclusion in meta-analysis. These were 'immediate outcome' data relating to Independence in ADL for 28 studies; motor function for 28 studies; balance for one study and gait velocity for three studies. Three of these studies reported length of stay. 'Persisting outcome' data were available relating to independence in ADL for 10 studies; motor function for 10 studies; balance for one study and gait velocity for three studies. (See Table 4 for further details.)

Intervention versus attention control or usual care

Of the 27 studies included in this review that compared an active intervention with usual care (17) or attention control (10), 22 included data suitable for inclusion in meta-analysis. These were 'immediate outcome' data relating to independence in ADL for eight studies; motor function for 13 studies; balance for six studies and gait velocity for 16 studies. Two of these studies reported length of stay. 'Persisting outcome' data were available relating to independence in ADL for no studies; balance for no studies; balance for four studies; balance for no studies and gait velocity for six studies. (See Table 5 for further details.)

One active intervention versus another active intervention

Of the 23 studies included in this review that compared two different active interventions, 13 included data suitable for inclusion in meta-analysis. These were 'immediate outcome' data relating to independence in ADL for seven studies; motor function for eight studies; balance for four studies and gait velocity for seven studies. Four of these studies reported length of stay. 'Persisting outcome' data were available relating to independence in ADL for two studies; motor function for no studies; balance for no studies and gait velocity for two studies. (See Table 6 for further details.) Data from three studies comparing one active intervention with another active intervention (Chen 2006; Cooke 2006; Jing 2006) were available but were not included in meta-analyses, as the two active treatment groups were classified as including similar treatment components.

Excluded studies

Studies listed in the Characteristics of excluded studies table were limited to those for which discussions were required between review authors to reach consensus. Thirty-nine studies are listed; we considered a further 147 as full papers but excluded them, as we agreed that they clearly did not meet the inclusion criteria. We needed to look at full papers because insufficient details were provided in the abstracts; the main reasons for excluding studies at this stage were that they were not randomised controlled trials (RCTs) or that they investigated a single specific treatment (such as electrical stimulation or treadmill training).

Risk of bias in included studies

Details of the methodological quality of the studies are provided in Characteristics of included studies, and risk of bias is summarised in Figure 3 and Figure 4. We assessed only 40 of the 99 studies to have low risk of bias for sequence generation; 29 of 99 for allocation concealment and 51 of 99 for blinding of outcome assessor. Poor reporting led to our assigning 'unclear' risk of bias in most cases, with 56 of 99, 59 of 99 and 39 of 99 studies having unclear risk of bias for sequence generation, allocation concealment and blinding of outcome assessor, respectively. We assessed a larger proportion (72 of 99) to have low risk of bias for being 'free of systematic differences in baseline characteristics of groups,' as this information could generally be determined from tables of characteristics of participants. When no systematic differences in baseline characteristics of groups were noted, there was no need for study authors to adjust for baseline characteristics; this was also therefore assessed to show low risk of bias for a similar number of studies.

Figure 3. Risk of bias graph: review authors' judgements about each risk of bias item presented as percentages across all included studies.

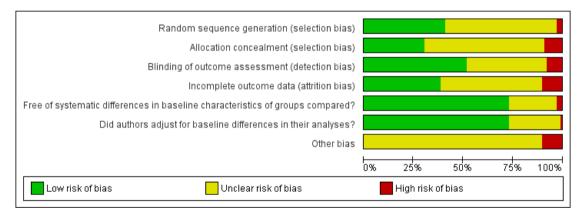

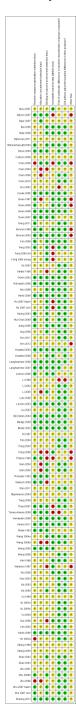

Figure 4. Risk of bias summary: review authors' judgements about each risk of bias item for each included study.

Effects of interventions

See: Summary of findings for the main comparison Summary of findings: intervention versus no treatment; Summary of findings 2 Summary of findings: intervention versus usual care or attention control; Summary of findings 3 Summary of findings: one active intervention versus another active intervention

The results are described below under the comparisons carried out for each of the explored outcomes (1. Independence in ADL scale; 2. Motor function scale; 3. Balance; 4. Gait velocity and 5. Length of stay) for both immediate and persisting outcomes. Table 12 provides a summary of the analyses performed, stating the numbering of analyses; Table 13 provides a summary of the subgroup analyses performed, along with the numbering of subgroup analyses.

(Section numbering corresponds to numbering of relevant analyses. Four 'empty' forest plots are provided, for which no data were available. These include the following: Analysis 5.1-Intervention versus usual care; persisting outcomes-global dependency; Analysis 5.3-Intervention versus usual care; persisting outcomesbalance; Analysis 6.2-One intervention versus another; persisting outcomes-functional independence and Analysis 6.3-One intervention versus another; persisting outcomes-balance. Despite the absence of data, these forest plots have been left, as this maintains the consistency of numbering of the section headings and analyses, which we believe aids the accessibility of this section.)

I. Comparison I. Intervention versus no treatment, immediate outcomes

I.I. Independence in ADL scale

We pooled data from 27 studies (3423 participants) in the analysis, demonstrating that the intervention had a significantly beneficial effect compared with no intervention (SMD 0.78, 95% CI 0.58 to 0.97). However, substantial heterogeneity was found ($I^2 = 85\%$). Significant differences were noted between the subgroups of different categories of treatment components (P value < 0.00001). For the subgroup of studies that combined functional task training and musculoskeletal components (Analysis 1.1.2; nine studies, 967 participants) and for studies that combined functional task training and neurophysiological and musculoskeletal components (Analysis 1.1.6; 12 studies, 1838 participants), a significant effect of the intervention compared with no intervention was seen (SMD 0.97, 95% CI 0.67 to 1.27, $I^2 = 76\%$; and SMD 0.96, 95% CI 0.66 to 1.27, $I^2 = 86\%$, respectively). See Analysis 1.1.

Sensitivity analysis: risk of bias

Removing studies judged to be at high risk of bias for at least one assessed quality of component led to our removing Chu 2003,

Fang 2003, Fang 2004 old, Fang 2004 young, Hu 2007 haem, Hu 2007 isch, Li 1999, Wu 2006, Xue 2006, Yin 2003a and Zhu 2006. Data from the remaining 17 studies (2655 participants) demonstrated a similar direction of effect (SMD 0.98, 95% CI 0.63 to 1.34, $I^2 = 94\%$); additionally, removing the studies for which data had been estimated from reported ranges (Green 2002; Zhu 2007 haem; Zhu 2007 isch) left data from 15 studies (2346 participants), demonstrating a similar direction of effect (SMD 1.07, 95% CI 0.66 to 1.47, $I^2 = 95\%$).

Removing all studies judged as having unclear or high risk of bias for random sequence generation or allocation concealment left only two studies (Green 2002; Wade 1992; 150 participants), which showed no significant benefit of intervention versus no treatment (SMD -0.06, 95% CI -0.30 to 0.19, $I^2 = 0\%$). (These sensitivity analyses are not illustrated within forest plots.)

Subgroup analysis: time after stroke

A significant difference between subgroups was noted according to time post stroke (P value 0.003), with a suggestion of greater effect in studies with participants who were within 30 days post stroke. See Analysis 7.1.

Subgroup analysis: study geographical location

Twenty-five (3173 participants) of the 27 studies were carried out in China, and only two studies (250 participants) were carried out in Europe (Green 2002; Wade 1992). A significant difference between these subgroups was noted (P value < 0.00001). See Analysis 7.2.

Subgroup analysis: dose of intervention

Eight studies (711 participants) provided the intervention more than once per day; 11 studies (1027 participants) provided daily intervention five to seven days per week for between 30 and 60 minutes; four studies provided a less frequent intervention than this and the dose was not stated in another four studies (see Table 10). When the studies in which the dose was not stated were excluded (as it was not appropriate to include this group), a significant difference between subgroups was noted (P value < 0.00001) (analysis not shown). A significant difference was also seen between the subgroup of more than one intervention per day and the subgroup receiving daily intervention (P value 0.02) (analysis not shown). The effect size was greater in studies with a greater dose of intervention, with an indication that a dose of between 30 and 60 minutes once per day for five to seven days a week was beneficial, but that more than once-daily intervention may provide even greater benefit. See Analysis 7.3.

Sensitivity analysis: dose and duration of the intervention period

We explored the effect of the length of the intervention period for studies that provided the intervention once per day or provided daily interventions five to seven days per week for between 30 and 60 minutes (19 studies). The order of these studies within Analysis 7.3.1 and 7.3.2 is from least to most intervention (with studies for which length of intervention is not stated at the 'most' end). Six studies did not state the length of intervention and were removed from the analysis (Pan 2004; Xie 2003; Zhang 1998; Zhu 2006; Zhu 2007 haem; Zhu 2007 isch). Four studies (298 participants) (Fang 2004 old; Fang 2004 young; Liu 2003; Pang 2006) had a length of intervention of 15 days or less: including only these studies leads to a non-significant effect (SMD 0.54, 95% CI -0.01 to 1.09), but with very substantial heterogeneity ($I^2 = 80\%$). Eight studies (938 participants) (Huang 2003; Li 1999; Xu 1999; Xu 2003b; Xu 2004; Xue 2006; Yan 2002; Zhao 2003) had a length of intervention of approximately one month; including only these studies demonstrated a significant effect of the intervention (SMD 1.06, 95% CI 0.63 to 1.48), with very substantial heterogeneity $(I^2 = 88\%)$. (These sensitivity analyses are not illustrated within forest plots.)

Subgroup analysis: provider of the intervention

Five studies (1158 participants) stated that the intervention was provided by a 'therapist'; six studies (429 participants) stated that it was provided by a therapist with help from family members (although in three of these studies, the role of the 'therapist' is not explicit; Xu 1999; Xu 2004; Zhang 1998). Two of the studies stated that it was a 'physiotherapist' and two stated 'nurse' or 'rehabilitation nurse.' In some cases it was stated that another professional, such as an occupational therapist (Wade 1992) or a doctor (Zhang 2004), also contributed. The provider was not stated in 12 studies. When studies in which the provider was not stated were excluded (as it was not appropriate to include this group), a significant difference between subgroups was noted (P value 0.0001) (analysis not shown), with an indication of greater effect when the provider was 'therapist' or 'therapist plus family.' However, each of the other subgroups contained only two studies. See Analysis 7.4.

Subgroup analysis: treatment components included

Twenty-three studies (3055 participants) included functional task training components; 15 studies (2106 participants) included neurophysiological training components and 23 studies (3033 participants) included musculoskeletal components. No significant difference between these subgroups was observed (P value 0.99). See Analysis 7.5.

I.2. Motor function scale

We pooled data from 25 studies (4558 participants) in the analysis, demonstrating that the intervention had a significantly beneficial effect compared with no intervention (SMD 0.81, 95% CI 0.58 to 1.04). However, considerable heterogeneity was present ($I^2 =$ 92%). Significant differences between the subgroups of different categories of treatment components were noted (P value < 0.0001). See Analysis 1.2.

Sensitivity analysis: risk of bias

Removing studies judged to be at high risk of bias for at least one assessed quality of component led us to remove Chu 2003, Fang 2003, Fang 2004 old, Hu 2007 isch, Li 1999, Xue 2006, Yin 2003a and Zhu 2006. Data from the remaining 18 studies (2655 participants) demonstrated a similar direction of effect (SMD 0.95, 95% CI 0.60 to 1.29, $I^2 = 93\%$); additionally removing the studies for which data had been estimated from reported ranges (Green 2002; Zhu 2007 isch; Zhu 2007 haem) left data from 15 studies (2416 participants), also demonstrating a similar direction of effect (SMD 1.02, 95% CI 0.63 to 1.14, $I^2 = 94\%$). Removing the one study that was visually a clear outlier (Zhao 2002) left 14 studies (2236 participants) and still demonstrated a similar direction of effect (SMD 0.79, 95% CI 0.54 to 1.03, $I^2 = 84\%$). Removing all studies judged as having unclear or high risk of bias for random sequence generation or allocation concealment

left only two studies (Green 2002; Wade 1992; 250 participants), which showed no significant benefit of intervention versus no treatment (SMD 0.14, 95% CI -0.31 to 0.58, $I^2 = 67\%$). (These sensitivity analyses are not illustrated within forest plots.)

Subgroup analysis: time after stroke

A significant difference between subgroups was noted according to time post stroke (P value 0.02). However, when studies in which the time after stroke was not stated were excluded, no significant difference between subgroups was noted (P value 0.06) (analysis not shown). See Analysis 9.1.

Subgroup analysis: study geographical location

Twenty-three (4308 participants) of the 25 studies were carried out in China, and only two studies (250 participants) were carried out in Europe (Green 2002; Wade 1992). A significant difference between these subgroups was reported (P value 0.005). See Analysis 9.2.

Subgroup analysis: dose of intervention

Four studies (434 participants) provided the intervention more than once per day; 11 studies (1080 participants) provided daily intervention five to seven days per week for between 30 and 60

minutes; five studies provided less frequent interventions than this and the dose was not stated in another four studies (see Table 10). When studies in which the dose was not stated were excluded (as it was not appropriate to include this group), a significant difference between subgroups was noted (P value 0.0007) (analysis not shown). However, no significant differences between the subgroup of more than one intervention per day and the subgroup receiving daily intervention was noted (P value 0.20) (analysis not shown). The effect size was greater with studies with a greater dose of intervention, with an indication that a dose of at least 30 to 60 minutes once per day for five to seven days a week was beneficial. See Analysis 9.3.

Sensitivity analysis: dose and duration of the intervention period

We explored the effect of the length of the intervention period for studies that provided the intervention once per day or provided daily intervention five to seven days per week for between 30 and 60 minutes (17 studies). The order of these studies within Analysis 9.3.1 and 9.3.2 is from least to most intervention (with studies for which length of intervention is not stated at the 'most' end). Seven studies did not state the length of intervention, and we removed them from the analysis (Pan 2004; Yin 2003a; Zhang 1998; Zhu 2001; Zhu 2006; Zhu 2007 haem; Zhu 2007 isch). Three studies (220 participants) (Fang 2004 old; Fang 2004 young; Liu 2003) had a length of intervention of 15 days or less; including only these studies leads to a non-significant effect (SMD 0.71, 95% CI -0.36 to 1.79), but with very substantial heterogeneity ($I^2 =$ 92%). Six studies (716 participants) (Chu 2003; Huang 2003; Wang 2004a; Xu 2003b; Xue 2006; Zhao 2002) had a length of intervention of approximately one month; including only these studies demonstrates a significant effect of intervention (SMD 1.45, 95% CI 0.39 to 2.51), with very considerable heterogeneity (I² = 97%). (These sensitivity analyses are not illustrated within forest plots.)

Subgroup analysis: provider of the intervention

Seven studies (1356 participants) stated that the intervention was provided by a 'therapist'; two studies (152 participants) stated that it was provided by a therapist with help from family members (although the role of the 'therapist' was not explicit in Zhang 1998). Two of the studies stated that it was a 'physiotherapist' and three stated 'nurse' or 'rehabilitation nurse.' In some cases it was stated that another professional, such as an occupational therapist (Wade 1992) or a doctor (Zhang 2004), also contributed. The provider was not stated in 11 studies. When studies in which the provider was not stated were excluded (as it was not appropriate to include this group), a significant difference between subgroups was noted (P value 0.004) (analysis not shown). However, excluding the group stating 'physiotherapist' demonstrated no significant difference between the remaining groups (P value 0.15) (analysis not shown). See Analysis 9.4.

Subgroup analysis: treatment components included

Twenty-three studies (4330 participants) included functional task training components; 13 studies (2033 participants) included neurophysiological training components and 22 studies (4240 participants) included musculoskeletal components. No significant differences between these subgroups were reported (P value 0.74). See Analysis 9.5.

I.3. Balance (Berg Balance Scale)

Only one study (34 participants) reported a Berg Balance Scale score for a comparison of intervention versus no treatment (SMD -0.04, 95% CI -0.71 to 0.64).

I.4. Gait velocity

Three studies (292 participants), all investigating functional task training interventions, reported gait velocity, demonstrating no significant benefit of intervention compared with no treatment (SMD 0.05, 95% CI -0.18 to 0.28), with no statistical heterogeneity ($I^2 = 0\%$).

1.5. Length of stay

Three studies (318 participants), all investigating functional task training plus musculoskeletal interventions, reported length of stay. Analysis demonstrated no statistically significant effect of the intervention on length of stay (MD -2.85, 95% CI -10.47 to 4.76), with very considerable heterogeneity ($I^2 = 96\%$).

2. Comparison 2. Intervention versus attention control or usual care, immediate outcomes

2.1. Independence in ADL scale

We pooled data from six studies (260 participants) in this analysis. For all six studies, the control intervention was categorised as 'usual care' and the intervention was given in addition to this usual care. Two studies each compared two active intervention groups with usual care; both active intervention groups were included in the analysis, with the control group participants 'shared' between these comparisons (Mudie 2002; Richards 1993). The meta-analysis found no evidence that the addition of the active intervention had any significant effect compared with usual care only (SMD 0.04, 95% CI -0.27 to 0.35), with low heterogeneity ($I^2 = 21\%$). See Analysis 2.1.

Sensitivity analysis: comparison group

The comparison group was classed as usual care for five studies and as attention control for one study (Chen 2010). In two studies the usual care was categorised as comprising neurophysiological components (Pollock 1998; Richards 1993); in one study it was categorised as comprising functional task training and neurophysiological and musculoskeletal components (Duncan 1998). No details of the usual care were provided for Mudie 2002 or for Langhammer 2007. The attention control intervention in another study was Traditional Chinese Medicine (TCM) massage therapy (Chen 2010). Sensitivity analyses to explore the effects of these different types of 'usual care' or attention control found no effect on the direction of these results, although it was noted that the study with the TCM massage therapy comparison intervention (Chen 2010; 106 participants) did find a significant benefit of active intervention as compared with TCM massage therapy (SMD 0.53, 95% CI 0.14 to 0.92). (These sensitivity analyses are not illustrated within forest plots.)

Sensitivity analysis: risk of bias

Removing studies judged to be at high risk of bias for at least one assessed quality of component led to the removal of Pollock 1998 but did not alter the direction of the results (SMD 0.03, 95% CI -0.32 to 0.38); additionally removing Chen 2010, as these data were estimated from categorical data, did not alter the direction of the results (SMD -0.19, 95% CI -0.53 to 0.15). (These sensitivity analyses are not illustrated within forest plots.) No further studies were removed by excluding those judged as unsure or high risk of bias for random sequence generation or allocation concealment.

Subgroup analysis: time after stroke

A significant difference between subgroups was noted according to time post stroke (P value 0.05), suggesting that a greater effect may occur with a smaller time after stroke. See Analysis 8.1.

Subgroup analysis: study geographical location

A significant difference between subgroups was noted based on study geographical location (P value 0.04). The only study with a positive effect was carried out in China. See Analysis 8.2.

Subgroup analysis: dose of intervention

Two studies (46 participants) provided daily intervention five to seven days per week for between 30 and 60 minutes; two studies (85 participants) provided two to three interventions per week and the dose was not stated in another three studies (see Table 11). When studies in which the dose was not stated were excluded (as it was not appropriate to include this group), no significant difference between subgroups was noted (P value 0.58) (analysis not shown). See Analysis 8.3. Data were insufficient to enable sensitivity analyses to explore length of intervention. The length of the intervention period in the four studies that stated this information was four weeks (Pollock 1998), six weeks (Mudie 2002), eight weeks (Duncan 1998) and four three-month sessions (Langhammer 2007).

Subgroup analysis: provider of intervention

Four studies (124 participants) stated that the intervention was provided by a 'physiotherapist'; one study stated that it was a 'Bobath-trained physiotherapist.' In Duncan 1998 an occupational therapist also contributed. The provider was not stated in one study. When studies in which the provider was not stated were excluded (as it was not appropriate to include this group), no significant difference between subgroups was noted (P value 0.43) (analysis not shown). See Analysis 8.4.

Subgroup analysis: treatment components included

Six studies (244 participants) included functional task training components; three studies (54 participants) included neurophysiological training components and four studies (208 participants) included musculoskeletal components. No significant difference between these subgroups was reported (P value 0.58). See Analysis 8.5.

2.2. Motor function scale

We pooled data from 13 studies (967 participants) in this analysis. Each of two studies compared two active intervention groups with usual care; both active intervention groups were included in the analysis, and the control group participants were 'shared' between these comparisons (Cooke 2006; Richards 1993). Meta-analysis demonstrated a significant effect of intervention compared with usual care (SMD 0.42, 95% CI 0.24 to 0.61), with moderate heterogeneity ($I^2 = 42\%$).

Significant differences between the subgroups of different categories of treatment components were noted (P value 0.02), with some indication of greater effect when neurophysiological components were included.

For the subgroup of studies that combined functional task training and neurophysiological and musculoskeletal components (Analysis 2.2.6; four studies, 281 participants), a significant effect of intervention compared with usual care was reported (SMD 0.46, 95% CI 0.21 to 0.70), with no statistical heterogeneity ($I^2 = 0\%$). See Analysis 2.2.

Sensitivity analysis: comparison group

The comparison group was classed as usual care for 11 studies and as attention control for two studies. Usual care included both functional task training and neurophysiological components (plus other components) for four studies (Cooke 2006; Duncan 1998;

Qian 2005; Tang 2009); functional task training (plus other components) for two studies (Duncan 2003; Kwakkel 2008); neurophysiological (with or without other components) for one study (Richards 1993); musculoskeletal (passive) for one study (Wang 2004b) and was not described for three studies (Langhammer 2007; McClellan 2004; Wei 1998). The attention control was TCM massage therapy for one study (Chen 2010) and a social intervention for another study (Mudge 2009). Sensitivity analyses to explore the effects of these different types of 'usual care' or attention control found no effect on the direction of these results. (These sensitivity analyses are not illustrated within forest plots.)

Sensitivity analysis: risk of bias

Removing studies judged to be at high risk of bias for at least one assessed quality of component led to the removal of Duncan 1998, Duncan 2003 and Qian 2005, and left data from nine studies (733 participants), which did not alter the direction of the results (SMD 0.31, 95% CI 0.13 to 0.49); additionally removing Mudge 2009 (as these data were estimated from the range) and Chen 2010 (as these data were estimated from categorical data) did not alter the direction of the results (seven studies, 569 participants; SMD 0.31, 95% CI 0.10 to 0.53).

However, removing all studies judged as unclear or high risk of bias for random sequence generation or allocation concealment led to the removal of Chen 2010, Kwakkel 2008, Qian 2005, Tang 2009, Wang 2004b and Wei 1998, leaving seven studies (377 participants) and demonstrating no significant effect of intervention compared with usual care or control (SMD 0.17, 95% CI -0.04 to 0.38), with no statistical heterogeneity ($I^2 = 0\%$). (These sensitivity analyses are not illustrated within forest plots.)

Subgroup analysis: time after stroke

No statistically significant difference between subgroups was noted according to time post stroke (P value 0.34). See Analysis 10.1.

Subgroup analysis: study geographical location

Five studies (348 participants) were carried out in China; three (405 participants) in Europe; three (75 participants) in North America and Canada and two (79 participants) in Austalia and New Zealand. A significant difference between these subgroups was reported (P value 0.002), with studies carried out in China having a greater effect size. See Analysis 10.2.

Subgroup analysis: dose of intervention

No studies provided the intervention more than once per day; four studies (242 participants) provided daily intervention five to seven days per week for between 30 and 60 minutes; four studies (269 participants) provided intervention three or four times per week and three studies (327 participants) provided intervention twice weekly (see Table 11). The dose was not stated in another two studies. When studies in which the dose was not stated were excluded (as it was not appropriate to include this group), a significant difference between subgroups was noted (P value 0.002) (analysis not shown), with a greater effect size in studies with a greater dose of intervention. No significant difference between the subgroup of three to four interventions per week and the subgroup with one to two interventions per week was reported (P value 0.39) (analysis not shown). See Analysis 10.3.

Sensitivity analysis: dose and duration of intervention period

The effect of the length of the intervention period was explored by ordering studies within Analysis 9.3 from least to most intervention (with studies in which length of intervention is not stated at the 'most' end). One study did not state the length of intervention (Qian 2005) and was removed from the analyses. Four studies (228 participants) (Cooke 2006; McClellan 2004; Mudge 2009; Wang 2004b) had a length of intervention of four to six weeks; including only these studies leads to a non-significant effect (SMD 0.22, 95% CI -0.08 to 0.51), with low heterogeneity (I² = 14%). Five studies (504 participants) (Duncan 1998; Duncan 2003; Kwakkel 2008; Tang 2009; Wei 1998) had a length of intervention of eight to 14 weeks; including only these studies demonstrates a significant effect of intervention (SMD 0.57, 95% CI 0.34 to 0.80), with moderate heterogeneity (I² = 31%). (These sensitivity analyses are not illustrated within forest plots.)

Subgroup analysis: provider of intervention

Eight studies (619 participants) stated that the intervention was provided by a 'physiotherapist'; two stated the provider was a 'therapist' and one a 'nurse.' In Duncan 1998 and Duncan 2003, an occupational therapist also contributed; in Kwakkel 2008 a sports therapist contributed and in Mudge 2009, physiotherapy students contributed. In Cooke 2006 the provider was described as a 'research physiotherapist.' The provider was not stated in two studies. When studies in which the provider was not stated were excluded (as it was not appropriate to include this group), a significant difference between subgroups was reported (P value 0.02) (analysis not shown), but the low number of studies in some groups makes it difficult to determine the direction of effect. See Analysis 10.4.

Subgroup analysis: treatment components included

Eleven studies (827 participants) included functional task training components; eight studies (467 participants) included neurophysiological training components and 10 studies (818 participants) included musculoskeletal components. No significant difference between these subgroups was noted (P value 0.12). See Analysis 10.5.

2.3. Balance (Berg Balance Scale)

We pooled the data from five studies (246 participants) in this analysis. One study compared two active intervention groups with usual care; both active intervention groups were included in the analysis, with control group participants 'shared' between these comparisons (Richards 1993).

Meta-analysis demonstrated a significant effect of intervention compared with usual care (SMD 0.31, 95% CI 0.05 to 0.56), with no statistical heterogeneity ($I^2 = 0\%$).

No significant differences between the subgroups of different categories of treatment components were reported (P value 0.90). See Analysis 2.3.

Sensitivity analysis: comparison group

The comparison group was classed as usual care for four studies and as attention control for one study. The usual care included functional task training and neurophysiological components in one study (Duncan 1998), functional task training (plus other components) in two studies (Duncan 2003; Kim 2012) and only neurophysiological components in one study (Richards 1993). The attention control comprised upper limb training (Salbach 2004). Sensitivity analyses to explore the effects of these different types of 'usual care' or attention control found no effect on the direction of these results. (These sensitivity analyses are not illustrated within forest plots.)

Sensitivity analysis: risk of bias

Removing studies judged to be at high risk of bias for at least one assessed quality of component led to the removal of all studies apart from Richards 1993 and did not demonstrate a significant effect (SMD 0.40, 95% CI -0.48 to 1.28). However, removing all studies judged as unclear or high risk of bias for random sequence generation or allocation concealment led to the removal of only Kim 2012 and had no effect on the direction of the results. (These sensitivity analyses are not illustrated within forest plots.)

2.4. Gait velocity

We pooled data from 14 studies (1126 participants) in this analysis. Two studies compared two active intervention groups with usual care; both active intervention groups were included in the analysis, with control group participants 'shared' between these comparisons (Cooke 2006; Richards 1993).

Meta-analysis demonstrated a significant effect of intervention compared with usual care (SMD 0.46, 95% CI 0.32 to 0.60), with little heterogeneity ($I^2 = 14\%$).

No significant differences between the subgroups of different categories of treatment components were reported (P value 0.86). See Analysis 2.4.

Sensitivity analysis: comparison group

The comparison group was classed as usual care for seven studies and as attention control for seven studies. The usual care included functional task training and musculoskeletal and neurophysiological components in two studies (Cooke 2006; Duncan 1998), functional task training and musculoskeletal components for three studies (Behrman 2011; Duncan 2003; Kim 2012); functional task training and musculoskeletal and cardiopulmonary components for one study (Kwakkel 2008) and only neurophysiological components for one study (Richards 1993). The attention control comprised upper limb training for three studies (Blennerhassett 2004; Dean 2000; Dean 2006); cognitive training for two studies (Dean 1997; Dean 2007) and a social intervention for one study (Mudge 2009). Sensitivity analyses to explore the effects of these different types of 'usual care' or attention control found no effect on the direction of these results. When only the studies with attention control comparisons were included, seven studies (251 participants) found a significant effect in favour of the intervention compared with attention control (SMD 0.41, 95% CI 0.15 to 0.67), with low heterogeneity ($I^2 = 20\%$). When only the studies with usual care comparisons were included, seven studies (775 participants) also found a significant effect in favour of the intervention compared with usual care (SMD 0.50, 95% CI 0.34 to 0.67), with low heterogeneity ($I^2 = 9\%$). (These sensitivity analyses are not illustrated within forest plots.)

Sensitivity analysis: risk of bias

Removing studies judged to be at high risk of bias for at least one assessed quality of component led to the removal of Dean 1997, Dean 2000, Duncan 1998, Duncan 2003 and Kim 2012, leaving data from eight studies (876 participants), which did not alter the direction of the results (SMD 0.53. 95% CI 0.39 to 0.67); additionally removing Mudge 2009 (as these data were estimated from the range) did not alter the direction of the results (seven studies, 818 participants; SMD 0.52, 95% CI 0.35 to 0.68). Removing all studies judged as unclear or high risk of bias for random sequence generation or allocation concealment led to the removal of Behrman 2011, Dean 1997, Dean 2000, Kim 2012 and Kwakkel 2008, leaving nine studies (568 participants), and did not alter the direction of the results (SMD 0.42, 95% CI 0.25 to 0.59). (These sensitivity analyses are not illustrated within forest plots.)

2.5. Length of stay

Two studies (105 participants), both investigating functional task training plus musculoskeletal interventions, reported length of stay. This analysis demonstrated no statistically significant effect of intervention on reported length of stay (MD -10.36, 95% CI -48.09 to 27.36), with substantial heterogeneity ($I^2 = 83\%$). See Analysis 2.5.

3. Comparison 3. One active intervention versus another active intervention, immediate outcomes

3.1. Independence in ADL scale

3.1.1. Includes functional task training versus does not include functional task training

Four studies (186 participants) compared a group receiving an intervention that contained functional task training components with a group receiving an alternative intervention. In all four studies, the alternative intervention comprised neurophysiological components (Langhammer 2000; Lincoln 2003; Mudie 2002; Richards 1993). Three of the studies investigated only functional task training components (Langhammer 2000; Lincoln 2003; Mudie 2002), and one investigated functional task training plus musculoskeletal components and modalities (Richards 1993). This analysis demonstrated no significant differences between interventions comprising the different types of components (SMD -0.03, 95% CI -0.37 to 0.32), with low heterogeneity (I² = 19%). Sensitivity analysis to remove the one study with additional components (Richards 1993) did not change the direction of the results. See Analysis 3.1.

Subgroup analysis: functional task training components

Analysis 11.1 explores the effect of different functional task training components. No significant differences between these subgroups were reported (P value 0.59).

3.1.2. Includes neurophysiological versus does not include neurophysiological

Seven studies (451 participants) compared a group receiving an intervention that contained neurophysiological components with a group that received an alternative intervention. Five of the studies investigated the effect of neurophysiological components only (Langhammer 2000; Lincoln 2003; Mudie 2002; Richards 1993; Zhuang 2012); one of the studies investigated neurophysiological components combined with functional task training, modalities and musculoskeletal (passive) (Li 2005) and one investigated neurophysiological plus functional task training (Gelber 1995). In all seven studies, the neurophysiological component included components described as 'Bobath.' In six of the studies, the alternative intervention included functional task training: functional task training only in three studies (Langhammer 2000; Lincoln 2003; Mudie 2002); functional task training plus musculoskeletal components in two studies (Gelber 1995; Richards 1993) and functional task training plus modalities in one study (Li 2005). In one study the alternative intervention was a modality (acupuncture) (Zhuang 2012). This analysis demonstrated no significant differences between interventions, which did or did not include neurophysiological/Bobath treatment (SMD -0.02, 95% CI -0.26 to 0.22), with low heterogeneity ($I^2 = 28\%$). Sensitivity analyses to explore the effects of different comparison components did not change the direction of the results. We preplanned sensitivity analysis to explore the effects of including Zhuang 2012, as the alternative intervention group did not receive active physical rehabilitation in addition to acupuncture; removing this study did not lead to significant differences in the direction of the results. See Analysis 3.1.

Subgroup analysis: neurophysiological components

Analysis 11.2 explores the effects of different neurophysiological components. No significant differences between these subgroups were noted (P value 0.45).

3.1.3. Includes musculoskeletal versus does not include musculoskeletal

Three studies (103 participants) compared a group that received an intervention containing musculoskeletal components with a group that received an alternative intervention. All three studies combined musculoskeletal components with components from other categories. Gelber 1995 and Richards 1993 combined both active and passive musculoskeletal components with functional task training and modalities or assistive devices. In both of these studies, the musculoskeletal components included muscle strengthening. Li 2005 implemented only passive musculoskeletal components (passive movement and body positioning) combined with functional task training, neurophysiological and modalities. The alternative intervention comprised only neurophysiological components in one study (Richards 1993); functional task training and neurophysiological in one study (Gelber 1995) and functional task training and modality in one study (Li 2005). This analysis demonstrated no significant differences between interventions that did or did not include musculoskeletal components (SMD -0.12, 95% CI -0.58 to 0.34), with low heterogeneity ($I^2 = 21\%$). Sensitivity analyses to explore the effects of different components did not change the direction of the results. See Analysis 3.1.

Subgroup analysis: musculoskeletal components

Analysis 11.3 explores the effects of different musculoskeletal components. No significant differences between these subgroups were reported (P value 0.11). However, this finding is based on a low number of studies.

Sensitivity analysis: risk of bias

Removing studies judged to be at high risk of bias for at least one assessed quality of component led to the removal of Gelber 1995 and Li 2005 and did not alter the direction of the results for any of the subgroups.

Removing studies judged as unclear or high risk of bias for random sequence generation or allocation concealment led to the removal of Li 2005 and did not alter the direction of the results. (These sensitivity analyses are not illustrated within forest plots.)

3.2. Motor function scale

3.2.1. Includes functional task training versus does not include functional task training

Four studies (188 participants) compared a group receiving an intervention that contained functional task training components with a group that received an alternative intervention. In all four studies, the alternative intervention comprised neurophysiological components (Langhammer 2000; Lincoln 2003; Richards 1993; Wang 2005). Two of the studies investigated only functional task training components (Langhammer 2000; Lincoln 2003); one investigated functional task training plus musculoskeletal components (Wang 2005) and one investigated functional task training plus musculoskeletal components and modalities (Richards 1993). This analysis demonstrated no significant differences between interventions comprising the different types of components (SMD -0.16, 95% CI -0.59 to 0.28), with moderate heterogeneity (I^2 = 45%). Sensitivity analyses to explore the effects of different components did not change the direction of the results. See Analysis 3.2.

Subgroup analysis: functional task training components

Analysis 12.1 explores the effects of different functional task training components. No significant differences between these subgroups were reported (P value 0.48).

3.2.2. Includes neurophysiological versus does not include neurophysiological

Eight studies (506 participants) compared a group that received an intervention containing neurophysiological components with a group that received an alternative intervention. Five of the studies investigated the effect of neurophysiological components only (Langhammer 2000; Lincoln 2003; Richards 1993; Wang 2005; Zhuang 2012); two of the studies investigated neurophysiological components combined with functional task training (Bale 2008; Gelber 1995) and one investigated neurophysiological components combined with functional task training and passive musculoskeletal components (Liao 2006). In all eight studies, the neurophysiological component included components described as 'Bobath.' In seven of the studies, the alternative intervention included functional task training: functional task training only in two studies (Langhammer 2000; Lincoln 2003); functional task training plus musculoskeletal components in three studies (Bale 2008; Liao 2006; Wang 2005) and functional task training plus musculoskeletal components and modalities or assistive devices in two studies (Gelber 1995; Richards 1993). In one study the alternative intervention was a modality (acupuncture) (Zhuang 2012). This analysis demonstrated no significant differences between interventions that did or did not include neurophysiological or Bobath treatment (SMD 0.17, 95% CI -0.05 to 0.39), with low heterogeneity (I² = 24%). Sensitivity analyses to explore the effects of different comparison components did not change the direction of the results. We preplanned a sensitivity analysis to explore the effect of including Zhuang 2012, as the alternative intervention group did not receive active physical rehabilitation in addition to acupuncture; removing this study did not result in significant differences in the direction of the results. See Analysis 3.2.

Subgroup analysis: neurophysiological components

Analysis 12.2 explores the effects of different neurophysiological components. No significant differences between these subgroups were reported (P value 0.76).

3.2.3. Includes musculoskeletal versus does not include musculoskeletal

Four studies (81 participants) compared a group that received an intervention containing musculoskeletal components with a group that received an alternative intervention. All four studies combined musculoskeletal components with components from other categories. Bale 2008 combined active musculoskeletal components with functional task training, and Gelber 1995, Richards 1993 and Wang 2005 combined both active and passive musculoskeletal components with functional task training (with or without modalities or assistive devices). In all four studies, the musculoskeletal components included muscle strengthening. The alternative intervention comprised only neurophysiological in two studies (Richards 1993; Wang 2005) and functional task training and neurophysiological in two studies (Bale 2008; Gelber 1995). This analysis demonstrated no significant differences between interventions that did or did not include musculoskeletal components (SMD -0.08, 95% CI -0.53 to 0.36), with no statistical heterogeneity ($I^2 = 0\%$). Sensitivity analyses to explore the effects of different components did not change the direction of the results. See Analysis 3.2.

Subgroup analysis: musculoskeletal components

Analysis 12.3 explores the effects of different musculoskeletal components. No significant differences between these subgroups were reported (P value 0.15). However, this finding is based on a low number of studies.

Sensitivity analysis: risk of bias

No studies were judged to be at high risk of bias for at least one assessed quality component. Removing Bale 2008, as these data were estimated from categorical data, did not alter the direction of the results.

Removing studies judged as unclear or high risk of bias for random sequence generation or allocation concealment led to the removal of Bale 2008, Gelber 1995 and Liao 2006 from the analyses but did not alter the direction of the results. (These sensitivity analyses are not illustrated within forest plots.)

3.3. Balance (Berg Balance Scale)

Four studies (83 participants) compared one active intervention with another active intervention and reported a measure of balance (Brock 2005; Richards 1993; Shin 2011; Wang 2005). No significant differences were found for comparisons of interventions containing different categories of treatment components (see Analysis 3.3).

3.4. Gait velocity

3.4.1. Includes functional task training versus does not include functional task training

Three studies (73 participants) compared a group receiving an intervention that contained functional task training components with a group that received an alternative intervention. In all three studies, the alternative intervention comprised neurophysiological components (Lincoln 2003; Richards 1993; Verma 2011). Two of the studies investigated only functional task training components (Lincoln 2003; Verma 2011), and one investigated functional task training plus musculoskeletal components and modalities (Richards 1993). This analysis demonstrated no significant differences between interventions comprising the different types of components (SMD 0.43, 95% CI -0.37 to 1.22), with substantial heterogeneity (I² = 73%). Sensitivity analyses to explore the effects of different components did not change the direction of the results. See Analysis 3.4.

3.4.2. Includes neurophysiological versus does not include neurophysiological

Seven studies (278 participants) compared a group receiving an intervention that contained neurophysiological components with

a group that received an alternative intervention. Four of the studies investigated the effect of neurophysiological components only (Lincoln 2003; Richards 1993; Thaut 2007; Verma 2011); two studies investigated neurophysiological components combined with functional task training (Bale 2008; Gelber 1995) and one investigated neurophysiological components combined with functional task training and cardiovascular training components (Brock 2005). In all seven studies, the neurophysiological component included components described as 'Bobath.' In all of the studies, the alternative intervention included functional task training: functional task training only in three studies (Lincoln 2003; Thaut 2007; Verma 2011); functional task training plus musculoskeletal components in one study (Bale 2008); functional task training plus musculoskeletal components and modalities or assistive devices in two studies (Gelber 1995; Richards 1993) and functional task training plus cardiovascular training components in one study (Brock 2005). Analysis demonstrated no significant differences between interventions that did or did not include neurophysiological or Bobath treatments (SMD -0.12, 95% CI -0.95 to 0.70), with substantial heterogeneity ($I^2 = 89\%$). Sensitivity analyses to explore the effects of different comparison components did not change the direction of the results. See Analysis 3.4.

3.4.3. Includes musculoskeletal versus does not include musculoskeletal

Three studies (45 participants) compared a group receiving an intervention that contained musculoskeletal components with a group that received an alternative intervention (Bale 2008; Gelber 1995; Richards 1993). Analysis demonstrated no significant differences between interventions that did or did not include musculoskeletal components (SMD -0.47, 95% CI -1.67 to 0.74), with substantial heterogeneity ($I^2 = 71\%$). Sensitivity analyses to explore the effects of different components did not change the direction of the results. See Analysis 3.4.

3.5. Length of stay

3.5.1. Includes functional task training versus does not include functional task training

One study (53 participants) compared a group receiving an intervention containing functional task training components with a group that received an alternative intervention. This study demonstrated that the functional task training intervention resulted in a reduced length of stay. See Analysis 3.5.

3.5.2. Includes neurophysiological versus does not include neurophysiological

Three studies (141 participants) compared a group receiving an intervention that contained neurophysiological components with

a group that received an alternative intervention. This analysis demonstrated a significantly reduced length of stay (MD 11.36, 95% CI 1.52 to 21.19) for the groups that did not receive the neurophysiological components, with substantial heterogeneity (I 2 = 74%). See Analysis 3.5.

3.5.3. Includes musculoskeletal versus does not include musculoskeletal

Two studies (88 participants) compared a group receiving an intervention that contained musculoskeletal components with a group that received an alternative intervention. This analysis demonstrated no significant differences between interventions that did or did not include musculoskeletal components (MD 8.71, 95% CI -12.92 to 30.34), with considerable heterogeneity ($I^2 = 91\%$). It should be noted that both of these studies are also included in comparison 3.5.2, but that Gelber 1995 compared musculoskeletal components with neurophysiological components, whilst Li 2005 combined musculoskeletal and neurophysiological components. See Analysis 3.5.

4. Comparison 4. Intervention versus no treatment, persisting outcomes

4.1. Independence in ADL scale

We pooled data from nine studies (540 participants) in this analysis, which demonstrated that intervention had a significantly beneficial effect compared with no intervention (SMD 0.58, 95% CI 0.11 to 1.04). However, substantial heterogeneity was found ($I^2 = 83\%$). See Analysis 4.1.

Significant differences between the subgroups of different categories of treatment components were found (P value 0.0002). These results are similar to the results for immediate Independence

in ADL outcomes (Analysis 1.1). Sensitivity analysis to explore the effects of studies with high or

uncertain risk of bias did not alter the direction of the results.

4.2. Motor function scale

We pooled data from eight studies (1829 participants) in this analysis, which demonstrated that intervention had a significantly beneficial effect compared with no treatment (SMD 1.06, 95% CI 0.37 to 1.75), with very considerable heterogeneity ($I^2 = 97\%$). Significant differences between the subgroups of different categories of treatment components were reported (P value 0.002). See Analysis 4.2.

Sensitivity analysis to explore the effects of studies with high or uncertain risk of bias demonstrated that the significant effect was not maintained if studies with high or uncertain risk of bias were removed (SMD 1.67, 95% CI -0.25 to 3.59).

4.3. Balance (Berg Balance Scale)

Only one study (Holmgren 2006) reported follow-up data for balance outcomes (see Analysis 4.3).

4.4. Gait velocity

The three studies that reported immediate outcomes for gait velocity also reported follow-up outcomes. Similar to the analysis of immediate outcomes, no statistically significant effect was found for intervention versus no treatment (SMD -0.06, 95% CI -0.29 to 0.18). See Analysis 4.4.

5. Comparison 5. Intervention versus attention control or usual care, persisting outcomes

5.1. Independence in ADL scale

No studies comparing intervention with control or usual care reported a follow-up outcome for an independence in ADL scale.

5.2. Motor function scale

We pooled data from three studies (160 participants) in this analysis, which demonstrated no significant differences between intervention and control (SMD -0.10, 95% CI -0.42 to 0.23), with no statistical heterogeneity ($I^2 = 0\%$). See Analysis 5.2.

5.3. Balance (Berg Balance Scale)

No studies comparing intervention with control or usual care reported a follow-up outcome for the Berg Balance Scale.

5.4. Gait velocity

We pooled data from five studies (214 participants) in this analysis, which demonstrates that intervention had a significantly beneficial effect compared with usual care or control (SMD 0.38, 95% CI 0.10 to 0.66), with no statistical heterogeneity ($I^2 = 0\%$). See Analysis 5.4.

This result is similar to the results for the immediate gait velocity outcomes (Analysis 1.4).

6. Comparison 6. One active intervention versus another active intervention, persisting outcomes

6.1. Independence in ADL scale

6.1.1. Includes functional task training versus does not include functional task training

One study (Verma 2011; 30 participants) compared a group receiving an intervention that contained functional task training components with a group that received an alternative intervention. This study did not contribute data to the analysis of immediate outcomes, as only follow-up data were provided. Follow-up was at six weeks, after a two-week intervention period. The data suggest a significant benefit of functional task training (SMD 1.33, 95% CI 0.52 to 2.13). See Analysis 6.1.

6.1.2. Includes neurophysiological versus does not include neurophysiological

Two studies (57 participants) compared a group receiving an intervention that contained neurophysiological components with a group that received an alternative intervention. This analysis demonstrated a significant detrimental effect of the intervention that included neurophysiological or Bobath treatments (SMD -0.95, 95% CI -1.67 to -0.22).See Analysis 6.1.

6.1.3. Includes musculoskeletal versus does not include musculoskeletal

One study (27 participants) compared a group receiving an intervention that contained musculoskeletal components with a group that received an alternative intervention. The data showed no significant differences between groups that did and did not receive musculoskeletal components (SMD 0.58, 95% CI -0.19 to 1.36). See Analysis 6.1.

Subgroup analysis

A statistically significant difference was reported between subgroups including different types of components (P value 0.0001), with an indication of greater beneficial effect of interventions that included functional task training or musculoskeletal components.

6.2. Motor function scale

No studies comparing two different active interventions reported a follow-up outcome for a motor function scale.

6.3. Balance (Berg Balance Scale)

No studies comparing two different active interventions reported a follow-up outcome for the Berg Balance Scale.

6.4. Gait velocity

6.4.1. Includes functional task training versus does not include functional task training

One study (Verma 2011; 30 participants) compared a group receiving an intervention that contained functional task training components with a group that received an alternative intervention containing neurophysiological components. This study did not contribute data to the analysis of immediate outcomes, as only follow-up data were provided. Follow-up was at six weeks, after a two-week intervention period. The data suggest significant benefits of functional task training (SMD 1.14, 95% CI 0.36 to 1.92). See Analysis 6.4.

6.4.2. Includes neurophysiological versus does not include neurophysiological

Two studies (43 participants) compared a group receiving an intervention that contained neurophysiological components with a group that received an alternative intervention (containing functional task training for Verma 2011 and functional task training plus musculoskeletal components for Gelber 1995). This analysis demonstrated a significant detrimental effect of the intervention that included neurophysiological or Bobath treatments (SMD -0.82, 95% CI -1.60 to -0.05). See Analysis 6.4.

6.4.3. Includes musculoskeletal versus does not include musculoskeletal

One study (14 participants) compared a group that received an intervention containing musculoskeletal components with a group that received an alternative intervention, which contained neurophysiological components. The data show no significant differences between groups that did and did not receive musculoskeletal components (SMD 0.33, 95% CI -0.74 to 1.40). See Analysis 6.4.

Subgroup analysis

A statistically significant difference was noted between the subgroups including different types of components (P value 0.002), with an indication of greater beneficial effect of interventions that included functional task training or musculoskeletal components.

ADDITIONAL SUMMARY OF FINDINGS [Explanation]

Physiotherapy intervention compared with usual care or attention control for recovery after stroke

Patient or population: adults with stroke Intervention: physiotherapy intervention Comparison: usual care or attention control

GRADE Working Group grades of evidence.

High quality: Further research is very unlikely to change our confidence in the estimate of effect.

Moderate quality: Further research is likely to have an important impact on our confidence in the estimate of effect and may change the estimate.

Low quality: Further research is very likely to have an important impact on our confidence in the estimate of effect and is likely to change the estimate.

Very low quality: We are very uncertain about the estimate.

DISCUSSION

Summary of main results

Key findings

This review included 96 studies (10,401 participants) that explored the effects of different physical rehabilitation approaches. More than half of the studies (50/99) were carried out in China. Fifty-one studies compared a physiotherapy intervention with no treatment; 42 of these studies were carried out in China. Twenty-seven studies compared a physiotherapy intervention with usual care or attention control. Twenty-four studies compared two different active physical rehabilitation approaches. Data were available for meta-analysis from 34 studies comparing intervention

with no treatment; 16 studies comparing intervention with usual care or attention control and 14 studies comparing two different active interventions. Key findings arising from meta-analyses were as follows.

Intervention versus no treatment

1. Moderate-quality evidence showed a beneficial effect of physical rehabilitation on measures of independence in ADL and motor function. This finding was sustained at follow-up assessments, although the size of the benefit was reduced. Quality of reporting of studies within this comparison was generally poor, and risk of bias was frequently unclear for key methodological criteria.

2. There was insufficient evidence to support conclusions relating to the effect of physical rehabilitation on balance, gait velocity or length of stay.

3. A significant difference between subgroups based on time since stroke was noted, with an indication of benefit associated with shorter time since stroke.

4. A significant difference between subgroups based on geographical location was reported, but most studies were carried out in China with participants who were within 30 days post stroke. All studies carried out in China were assessed at high or unclear risk of bias.

5. A significant difference between subgroups based on dose of intervention was noted, with an indication that a dose of between 30 and 60 minutes once per day for five to seven days a week was beneficial, but that more than once-daily intervention may provide even greater benefit. It was not possible to draw conclusions relating to duration of the intervention period, with substantial heterogeneity within analyses.

6. Significant differences between subgroups based on provider of intervention were noted, but it is difficult to reach generalised conclusions from these subgroup analyses.

7. Results of the subgroup analyses must be interpreted with caution, as a complex interrelationship between some of the subgroups is likely. For example, studies with the least time since stroke were carried out in China, meaning that reported effects attributed to geographical location may be related to time since stroke (and vice versa).

8. No significant differences were noted between studies that investigated different components or categories of intervention. In summary, moderate-quality evidence indicates that physical rehabilitation has a beneficial effect on independence in ADL and motor function after stroke, and that this effect persists beyond the end of the intervention period, when compared with no treatment. Evidence shows greater benefit associated with a shorter time since stroke. Evidence also suggests that a dose of 30 to 60 minutes per day delivered five to seven days per week is effective, and that more frequent or increased doses may provide even greater benefit. Substantial heterogeneity was observed between the studies included in these analyses, and most of the studies were at high or uncertain risk of bias.

This evidence principally arises from China, where a particular healthcare system and cultures and beliefs are associated with health and disease. In China, physiotherapy or rehabilitation traditionally has not been routinely provided within acute hospital settings; therefore this evidence is highly relevant to stroke care settings in China. Arguably this evidence does not have any direct implications for settings in which no treatment would not be considered to be an ethical alternative for hospitalised patients with stroke, but the indirect implications of this evidence base may have universal relevance. Evidence suggests that 30 to 60 minutes of physical rehabilitation per day, delivered five to seven days per week, is beneficial for recovery of function, but that no one individual approach to physical rehabilitation is better than any other approach.

Intervention versus usual care or attention control

1. Moderate- to high-quality evidence shows a beneficial effect of physical rehabilitation on measures of motor function, balance and gait velocity. Moderate-quality evidence also shows that this beneficial effect was maintained at follow-up for gait velocity, but insufficient data were available at follow-up to permit conclusions for other outcomes.

2. No evidence was found of any benefit of intervention on measures of independence in ADL, but relatively few studies included data for this outcome.

3. A significant difference between subgroups was noted based on time since stroke, with an indication of benefit associated with a shorter time since stroke. No evidence of this effect was seen in follow-up data.

4. For measures of motor function, a significant difference between subgroups based on dose of intervention was observed, with an indication that a dose of 30 to 60 minutes five to seven days per week was significantly more beneficial than an intervention delivered three to four times per week. No difference between subgroups was described for measures of independence in ADL. It was not possible to draw conclusions relating to duration of the intervention period, with substantial heterogeneity within analyses.

5. No significant differences were reported between studies that investigated different components or categories of intervention.

In summary, moderate- to high-quality evidence shows that physical rehabilitation is more effective than usual care or attention control in improving motor function, balance and gait velocity. Evidence suggests greater benefit associated with a shorter time since stroke. Evidence also suggests that a dose of 30 to 60 minutes delivered five to seven days a week provides significant benefit. In particular, high-quality evidence indicates that physical rehabilitation has an impact on gait, with significant increases in gait velocity maintained at follow-up assessments. Some evidence suggests that benefit may be greater if rehabilitation is carried out earlier after stroke, but these findings should be interpreted cautiously. As with the comparison of intervention versus no treatment, this evidence suggests that no one individual approach to physical rehabilitation is better than any other approach for recovery of function or mobility.

One active intervention versus another active intervention

1. Moderate-quality evidence shows no difference between interventions that include neurophysiological components and interventions that do not include neurophysiological components. This evidence primarily arose from interventions that were described as 'Bobath.' Very limited evidence indicates that interventions including neurophysiological components resulted in a longer hospital stay.

2. Low-quality evidence shows no differences between interventions that include components of functional task training and interventions that do not include components of functional task training. No evidence suggests that any specific functional task training components are more effective than other interventions.

3. Low-quality evidence shows no differences between interventions that include musculoskeletal components and interventions that do not include musculoskeletal components. No evidence suggests that any specific musculoskeletal components are more effective than other interventions. In summary, evidence suggests that no one physical rehabilitation approach is more effective in promoting recovery of function or mobility after stroke than any other approach. These findings are supported by the subgroup analyses carried out for the comparisons of intervention versus no treatment or usual care, which found no significant effects of different treatment components or categories of intervention.

Physical rehabilitation approaches and components synthesised within this review

This review synthesises evidence relating to the effectiveness of different physical rehabilitation approaches. The original focus of the comparisons within this review (2007 and earlier versions) was the effectiveness of different named approaches to physiotherapy, based on a historical perspective. The original review was carried out in direct response to a consultation exercise conducted in Scotland that aimed to identify the 'burning questions' of Scottish stroke rehabilitation workers, and that identified 'different (named) treatment approaches' to be amongst the most important questions posed by physiotherapists (Legg 2000). Following consultation with key stakeholders (physiotherapists, stroke survivors and carers), the focus for this update of the review was determined to be the individual treatment components that constitute physical rehabilitation approaches. This is an important, albeit arguably subtle, shift, enabling synthesis of evidence based on different philosophies and from different cultures, with systematic categorisation of individual treatment components, regardless of their philosophical or theoretical origin. This change in focus is in line with recommendations made within the 2007 version of this review.

The studies within this review included 121 active interventions; most of these (99 interventions) included treatment components categorised as functional task training. Most of the interventions incorporated treatment components from at least two different categories of intervention, with only 33 interventions focusing on just one category of intervention (20 interventions focused on functional task training only; 13 focused on neurophysiological interventions only). The finding that most studies include a combination of different treatment components, generally arising from at least two of the different categories defined for this review, highlights this fact: Physiotherapists appear to be basing their interventions not on one single historical or philosophical approach, but rather on a pragmatic eclectic approach that utilises a range of different treatment components, often regardless of their historical or philosophical origins. This pragmatic approach, which adopts a mix of components from different approaches, was supported by the previous version of this review, which concluded that a mix of components from different approaches was significantly more effective than no treatment or placebo in recovery of functional independence following stroke, and provides justification for the decision to change the focus of the review for this update.

Overall completeness and applicability of evidence

Identification of relevant trials

The identification of all relevant trials was confounded by several factors.

1. Inconsistent and poorly defined terminology: Electronic searching was difficult because the names given to different physiotherapy rehabilitation approaches are poorly documented, often have several derivations and have varied over time. Furthermore, the interventions were not always described as 'physiotherapy' or 'physical therapy,' but sometimes were described as 'rehabilitation,' 'training' or 'exercise.' This was particularly true for studies emerging from China, which frequently described interventions as 'early rehabilitation.' Studies investigating circuit training or exercise classes sometimes met the inclusion criteria for this review; again, identification of these was made difficult by lack of use of the term 'physiotherapy' or 'physical therapy.'

2. Change in focus of the review: As described above, for this update of the review, a subtle change in focus was applied-from 'named' rehabilitation approaches to the individual treatment components that constitute physical rehabilitation approaches. No change to the search strategy or to selection criteria was implemented, and we do not believe that any changes would be justified. It could be argued that decisions made relating to the exclusion of studies from the search results for previous versions of this review may be different in light of the changed focus. However, selection of relevant trials for this review has always been challenging, and we do not believe that the change in focus of the review has affected study selection in one direction or another.

3. Lack of detail within the abstracts: Lack of information on study methods, participants and interventions potentially increases the chance that a relevant trial may be excluded. However, when uncertainty arose, we obtained full papers.

4. Material published in journals not included in electronic databases, and unpublished material: Although substantial effort was made to identify unpublished material and material in journals not cited in the databases searched, relevant trials may not have been identified.

5. Material published in Chinese: A substantial number of the included studies were carried out in China and were published in Chinese. Our electronic searching successfully identified studies for which an abstract was available in Chinese, as well as a number of studies based on English titles. However, we believe it is likely that we will not have identified all relevant Chinese trials, in particular those for which only English titles were available and those not published in journals included in the electronic databases that we searched.

6. Different cultures and healthcare systems: Decisions were made to include some studies in which the provider of the intervention was not clearly a physiotherapist or a physical therapist; these decisions were often related to the fact that physiotherapists may not be routinely found in all healthcare settings around the world. This provided additional challenges in relation to determining whether a study was investigating a 'physical rehabilitation' approach. In particular, many studies in China simply referred to a 'therapist,' but in some instances, the provider was a doctor or a nurse. We carried out subgroup analyses to explore the effect of the stated intervention provider on outcome. However, many studies did not explicitly state this, which limited conclusions that could be made from this subgroup analysis.

Completeness of published studies

Many of the relevant trials that we included were published only as abstracts or as brief reports. This was frequently the case for studies published in Chinese, for which published versions were often less than two pages long. Although we contacted study authors, when possible, to confirm study eligibility, we did not have the time or resources to contact all study authors for further information on trial design or study results. Thus, in general the completeness of study information is low, resulting in a high number of studies for which risk of bias is classed as 'unclear' and a high number of studies that do not contribute data to the analyses.

Relatively few studies followed up with participants after the intervention had ended: Data were available immediately at the end of intervention for 49 studies for the independence in ADL outcome and for 50 studies for the motor function outcome, but only for 16 and 12 studies, respectively, for a longer-term follow-up outcome. Follow-up data from studies comparing intervention with no treatment demonstrate that significant benefit of intervention is maintained, but the size of the benefit was observed to lessen. In the comparison of intervention versus usual care or control, lack of follow-up data limits the ability of review authors to draw any generalisable conclusions relating to whether observed benefits are maintained.

Descriptions of interventions

Clear, concise documentation of complex physical interventions is exceptionally difficult to achieve. The written information provided by study authors regarding interventions administered in the included trials is included in the Characteristics of included studies table. Although many of the included studies attempt to describe all administered interventions, the available documentation is often insufficient to allow confident and accurate repetition of the applied rehabilitation approach. Problems with documentation of interventions generally are not the fault of researchers or therapists, but rather are due to the fundamental problem of recording methods of physical handling skills and techniques, and the nature of the often intimate relationship between stroke survivor and physiotherapist. Documentation of this process would generally be complex and 'wordy'; therefore often it is not possible to present within research papers with limitations on length. These problems are confounded by the fact that treatments applied are often ultimately the decision of a single physiotherapist, based on an individual assessment of a unique stroke survivor's movement disorders.

Furthermore, the common basis of physical rehabilitation 'approaches' is that they are holistic. All body parts and movements can be assessed and treated based on the selected approach; however, a physiotherapist may select to concentrate on the treatment of one particular body part or movement during a treatment session. Subsequently, treatments given to specific stroke survivors by individual therapists may vary enormously. This review attempted to limit this variation slightly by excluding trials that had provided interventions only to the upper limb. Nevertheless, although we grouped together studies that included treatment components within similar categories, it is conceivable that substantial differences exist between the physical interventions given to participants within the same treatment group.

Categorisation of treatment components within interventions

The comparisons carried out within the review relied on categorisation of treatment components that were described within the published papers. Two independent review authors categorised the described treatments using agreed definitions of individual treatment components. This process relied on adequate descriptions within published papers. Papers that published only very brief descriptions of interventions therefore may have resulted in categorisations that were not truly reflective of the intervention delivered. Furthermore, this process of categorisation was highly dependent on the language and terminology provided within a written de-

scription. For example, an author may state "activities aimed at improved gait." This description would result in categorisation only within the functional task training component of "walking." However, in practice, this intervention could have included components such as active or active-assisted movement, sensorimotor facilitation and muscle strengthening. Therefore our method of categorisation is likely to have underestimated rather than overestimated the numbers of treatment components and intervention categories. Hence, if any inaccuracy exists, the interventions are likely to be more "mixed" and eclectic than has been captured by our method of categorisation.

A number of difficulties were encountered in distinguishing between interventions that included only functional task training components and those that also included musculoskeletal (active) components. In particular, the review authors encountered difficulties in determining whether an intervention focused on a functional task might also include active or active-assisted movement. This reality was due to the fact that all functional task training necessitates active movement, and overlap between practice of an active-movement and practice of a functional task can be inevitable. This is an area that we recommend for further exploration in relation to the descriptions and definitions of treatment components proposed for this review.

Discussion also focused on whether the categories of 'assistive devices' and 'modalities' would be better combined into one joint category. The separate categories were agreed and defined by the stakeholder group participants, which is why they have been used within this review. However, we recommend that merging of these categories be explored before future updates of this review are prepared.

Treatment components within named approaches

We were aware when developing the definitions for categorisation of described interventions that a number of studies have stated a named approach (e.g. 'Bobath,' 'Motor-relearning programme') without providing any description of the treatment components included within the approach. We therefore wrote definitions such that these studies could be captured by our system of categorisation of individual treatment components. However, including studies that have provided only the name of an approach without providing any descriptions potentially introduces a number of biases. These biases occur as a result of the fact that the content of named approaches potentially changes over time and in keeping with geographical or personal preferences and biases. In particular, several studies reported that the intervention was 'Bobath,' and much debate has surrounded the content of physiotherapy interventions based on the Bobath concept. This debate arises largely from the fact that the content of the Bobath approach has changed over time, published descriptions are limited, and the content of current therapy is variable (Carr 1994a; DeJong 2004; Langhammer 2012; Mayston 2008; Nilsson 1992; Pomeroy 2001b; Sackley 1996; Tyson 2009b; Turner 1995). A summary of the philosophy or theory of some of the key named approaches was drawn up for the first version of this review and is provided in Table 1.

Translation of descriptions of interventions

Thirty-eight of the included full papers were published in languages other than English; all were published in Chinese. For these papers, we sought translation of the intervention description into English. In addition, several included studies were carried out in China and the papers published in English, but by authors for whom English clearly was not the first language. These translations provided a number of challenges in relation to interpretation of meanings and subsequent classification of treatment components. For example, in several papers, it was unclear whether 'standing up training' referred to activities carried out in standing (i.e. training to promote standing balance) or to sit-to-stand training. In these cases, decisions were made based on discussion between two review authors (one of whom was a Chinese-speaking physiotherapist (PLC)).

Geographical location of studies

Subgroup analyses found evidence of an association between effect size and geographical location, with an indication that studies carried out in China may have a greater effect size. This finding may be due to reporting biases and may reflect biases associated with publication, location, citation and language. This finding may also reflect a true difference in the effects of interventions carried out in different geographical locations, which may be a result of differences in culture, traditions, training and implementation of interventions. However, this difference may also be related to the comparison interventions, especially if they consist of no treatment or usual care. All studies that compared intervention against no treatment in the acute phase of stroke were carried out in China; this is a reflection of the fact that 'usual care' can comprise no rehabilitation within these geographical settings. Consequently, the finding that intervention is more effective than no treatment in improving independence in ADL and in motor function may, arguably, be applicable only to settings in China. Evidence shows that usual care can vary considerably, both regionally and nationally as well as internationally. Hence, geographical location could be a confounding variable in the comparison of intervention against usual care.

Quality of the evidence

Risk of bias of included studies

Judgement of quality of evidence was very difficult because of poor, incomplete or brief reporting of information. Less than 50% of the studies were judged to be at low risk of bias for selection, detection and attrition bias; however, for most of the studies, this information was unclear, and risk of bias was judged to be high in less than 10% of the studies. Sensitivity analyses were carried out to explore the effect of including studies with high or unclear risk of bias. These sensitivity analyses generally found that removal of studies with high or unclear risk of bias did not alter the direction (or significance) of the results. Thus, although the quality of most of the evidence included in this review remains uncertain, the fact that inclusion of these studies does not affect the direction of results gives us greater confidence in our findings. The main message arising from this review in relation to quality of the evidence is that it is essential that reporting of methodological features of RCTs of physiotherapy interventions is improved, and that studies are reported using the CONSORT guidelines for reporting (Schulz 2010).

Studies that used quasi-random assignment were excluded from this update of the review (previous versions had included quasirandomised trials). This led to exclusion of three studies that had been included in the 2007 version (Hesse 1998; Ozdemir 2001; Stern 1970). However, we found information about the method of randomisation particularly difficult to judge in a number of studies included in this review, particularly studies published in Chinese, in which use of the term 'random' in English abstracts did not always reflect the descriptions provided in Chinese versions of the study. There is an urgent need for trialists to address the issue of adequate reporting of methods of randomisation. It is possible that we have inadvertently included in this review trials that used quasi-random assignment, rather than true random assignment. In most studies, it was unclear whether participants were blinded to the study group and aims. The nature of rehabilitation interventions and the ethical requirement to obtain informed consent often make it difficult, if not impossible, to blind participants. If the aims and objectives of the study were apparent to the participants, this could confound the study results. It is generally impossible to blind the treating therapist because treating therapists have to be familiar with the intervention they are administering. Therapists who strongly favoured one approach over another could introduce performance bias. In several studies, the same therapist administered treatment to participants in both study groups; this potentially introduced considerable contamination between groups. The 'beliefs' of stroke survivors and therapists may further contribute to biases within many of these studies, and the large number of different geographical locations in which studies were carried out means that the studies were carried out with participants living in a wide variety of cultures, which could potentially impact the response to physical rehabilitation. Many of the included trials did not state that they used a blinded assessor. Lack of blinding of assessors potentially introduces considerable bias into the study results. This is particularly important in studies in which therapists often have strong beliefs in support of a particular approach.

Heterogeneity of included trials

In addition to limitations of the study methods, the trials included in the review had considerable heterogeneity. The key areas of heterogeneity were related to interventions and to participants.

1. Interventions: Although attempts have been made to categorise the interventions using a systematic, rigorous and valid method, considerable variation may still exist between studies that have used similar types of treatment components. Furthermore, substantial variations in dose and intensity and in length of the treatment period were noted. Also different is the fact that some interventions were carried out only when a therapist is present, whilst in other studies, independent practice of activities outside therapy sessions was encouraged.

2. Participants: The participant populations in the different included studies were heterogeneous. They varied from limited populations (e.g. pure motor stroke only) to those inclusive of all stroke survivors. Considerable variation in the time since stroke was also noted. The validity of combining results from such heterogeneous samples is debatable. We recommend that future updates consider subgroup analysis to explore the initial impairment of included participants.

Although we have carried out subgroup analyses to explore issues relating to the heterogeneity of both the interventions (i.e. dose, components) and the participants (time since stroke) and other issues (geographical location, provider of intervention), it is likely that a complex interrelationship exists between some of the subgroups that we have been unable to explore. For example, studies carried out in China tended to be those with the least time since stroke, meaning that effects found that have been attributed to geographical location could be due equally to time since stroke (and vice versa). We believe that this will be true for a number of other variables. We recommend that future updates of this review plan to explore issues associated with the interrelationship of these variables.

Potential biases in the review process

Publication bias

As has been discussed above, the identification of all relevant trials was confounded by a number of factors, and, despite a rigorous search strategy, we are not fully confident that we will have successfully identified all studies. Consequently, this review may be biased towards particular types of studies and publications. For example, we are not confident that we will have successfully identified all relevant studies published in China, or in Chinese. Similarly, we may be missing other non-English studies or studies published in

journals that are not included in the electronic databases that we searched.

Treatment components and categorisation of interventions

We introduced a method of categorisation of interventions that was agreed by a stakeholder group of physiotherapists, stroke survivors and carers. This method of categorisation has not been tested or explored further, and such testing is necessary to confirm the relevance and validity of the identified categories. In the absence of any other suitable method of categorisation of treatment components, we believe that we have adopted a robust, justifiable method-based on consensus between physiotherapists, stroke survivors and carers. We argue that the involvement of this expert stakeholder group has considerably enhanced our review and is substantially advantageous compared with the alternative of having researchers make decisions over the categorisation of interventions and the structure of comparisons. Feedback from the stakeholder group members confirms that the group perceived that their input benefited the format of the review and made the review more clinically relevant. However, because of the limited nature of our resources, most members of the stakeholder group were based in Scotland. Given known differences in physiotherapy practice in different parts of the world, we recommend that the proposed categorises are explored and amended to reflect international practices in relation to stroke rehabilitation.

We recognise that the terminology used, particularly in the titles of the categories, may not be universally accepted or understood. We acknowledge that the appropriateness of terms such as 'functional,' 'neurophysiological' and 'musculoskeletal' can be debated when used in the way we have used them within this review. However, these terms were selected by the stakeholder group to have clinical meaning and were informed by the terminology used by DeJong 2004.

Appraisal of quality in non-English language papers

Non-English (Chinese) papers included in the review were appraised and assessed for risk of bias by one review author with the language skills to translate relevant sections of the papers. This review author also possessed the necessary quality appraisal skills and had detailed expertise of physiotherapy and stroke rehabilitation. A second review author then considered the assessment of risk of bias by the first review author, based on the translations of relevant extracts provided by the first review author. Thus, although two review authors did consider the quality of these non-English language papers, the assessment of the second review author was based entirely on the translation provided by the first review author. This method means that if the first review author made any errors in translation, or missed information provided in the non-English text, the second review author will not have identified this. Thus, although having two review authors for these papers offers advantages, it does not provide the same level of 'independence' as the process of having two independent review authors for the English language papers. However, given the volume of non-English papers that we have included, and the available resources for this review, we believe that we have taken all steps available to us to minimise potential biases in this process.

Conclusions arising from this review

Following completion of the analyses and results of this review, this information was presented to our stakeholder group, which comprised physiotherapists, stroke survivors and carers. For each of the three main comparisons and associated subgroup analyses, group members discussed the clinical implications and key messages arising from the results. The points discussed have been incorporated within the Discussion and Authors' conclusions sections of this review. In particular, the stakeholder group members highlighted the need to specifically draw out information pertaining to the dose of interventions delivered within the studies, as this was believed to have important implications for clinical practice. We believe that this process of consultation considerably removes potential biases from the process of reaching conclusions from this review, as the conclusions reflect the views of expert clinicians, stroke survivors and carers, rather than the potentially biased viewpoints of researchers and academics.

Agreements and disagreements with other studies or reviews

Previous versions of this review

The previous (2007) version of this review concluded that "no one physiotherapy approach has been shown to be more advantageous to the promotion of recovery of lower limb function or postural control" and that "physiotherapy using a mix of components from different approaches is more beneficial than no treatment or placebo control for the recovery of functional independence after stroke." These findings supported the conclusion that "this evidence provides a sound scientific rationale for physiotherapists to use a selection of treatments, regardless of their philosophical or theoretical origin." This updated review agrees with, and adds considerable evidence to, these previous conclusions. Although the 2007 version concluded that evidence was insufficient to suggest that one approach was superior to another, this review can now conclude that moderate-quality evidence indicates that there is no difference between approaches.

Other reviews

A number of other published reviews agree with the conclusion that physiotherapists should not use compartmentalised, named approaches, but should select clearly defined and described techniques and task-specific treatments, regardless of their historical or philosophical origin (Kollen 2009; Langhammer 2012; Mayston 2008; Pomeroy 2005).

This review is in agreement with a review of evidence relating specifically to the Bobath approach (Kollen 2009), which concluded that there was "no evidence for the superiority of Bobath therapy or any other approach on sensorimotor control of the upper and lower limb, dexterity, mobility, ADL, HRQOL, and cost-effectiveness."

Zhang 2013 recently completed a review that has similarities to our comparison of physiotherapy treatment versus no treatment. Zhang 2013 aimed specifically to review RCTs that compared rehabilitation versus standard care after stroke in China. This review pooled evidence from 31 trials (5220 participants) that reported independence in ADL (Barthel Index) and 27 trials (4501 participants) that reported motor function (Fugl-Meyer Assessment). In contrast, we identified and pooled the results of 27 studies (3423 participants) and 25 studies (4558 participants), respectively. (NB: Our figures also include non-Chinese studies.) We are unclear whether the differences in included trials reflected a more effective strategy for identification of Chinese studies by Zhang 2013; differences in selection criteria between reviews or a combination of these. Before future updates of our review, we plan to speak to the authors of Zhang 2013 to discuss differences in identification and selection of trials between the reviews. Despite differences in the numbers of trials included, the results and conclusions of our review were in agreement with those of Zhang 2013, which concluded that "there is some evidence that rehabilitation post stroke is more effective than no rehabilitation, improving activities of daily living and reducing disability." Both Zhang 2013 and our review highlight the limitations relating to low reporting quality and study heterogeneity. A key difference between our review and Zhang 2013 is that Zhang 2013 did not attempt to explore the specific treatment components investigated by the studies.

AUTHORS' CONCLUSIONS

Implications for practice

Physical rehabilitation, using a mix of components from different approaches, is effective for recovery of function and mobility after stroke. Evidence relating to dose of physical rehabilitation is limited by substantial heterogeneity and does not support robust conclusions. However, there is some suggestion that treatment sessions of 30 to 60 minutes five to seven days a week may provide a beneficial effect, and more frequent sessions may provide added benefit. Evidence also suggests greater benefit associated with a shorter time since stroke. These hypotheses require robust evaluation before clinical recommendations can be made.

Current evidence indicates that no one approach to physical rehabilitation is more (or less) effective in promoting recovery of function and mobility after stroke. Therefore, clinical selection of the most appropriate physical treatments for individual stroke survivors should be undertaken using evidenced-based interventions and critical clinical reasoning. Members of the stakeholder group for this review agreed that key implications for practice arising from this evidence related to meeting the need for personnel involved in delivering stroke rehabilitation and educating therapists to:

1. select treatment components based on assessment of the individual stroke survivor, with consideration of the full range of treatment techniques that they have the skills and expertise to administer; and

2. implement evidence-based rehabilitation after stroke, with critical evaluation and awareness that the current evidence shows that no one approach is superior to any other.

In conclusion, this review provides evidence indicating that physical rehabilitation should not be limited to compartmentalised, named rehabilitation approaches, but should comprise clearly defined, well-described, evidence-based physical treatments regardless of historical or philosophical origin.

Implications for research

Moderate-quality evidence now shows that physiotherapy using a mix of components from different approaches is more beneficial than no treatment, usual care or attention control, and that no single approach is more (or less) effective than any other. Researchers should add to this body of evidence by determining which individual treatment components contribute towards the beneficial effects. High-quality randomised trials and systematic reviews are needed to determine the effectiveness of clearly described individual techniques and task-specific treatments, regardless of their historical or philosophical origin. Many Cochrane reviews have already been published that include a large body of trials exploring the effectiveness of specific single treatments, and it is important that researchers are familiar with this evidence and plan future research according to relevant recommendations within these reviews. Researchers should identify whether there are any gaps in this evidence base so that these can be addressed. It is important that the current Cochrane reviews are kept up-to-date. With a high volume of research being published in the Chinese literature, systematic reviewers must ensure that they have adequate resources to support review updates and to adequately address and explore the potential variations in clinical practice and trial design in studies arising from different geographical locations.

In addition to research evaluating single specific treatments, we recommend that researchers adopt pragmatic research designs to investigate the effectiveness of skilled physiotherapists in providing patient-centred interventions, for which treatment components are selected following individual patient assessment. Valid, reliable methods of systematic documentation and description of patientcentred physical rehabilitation must be explored, such that robust RCTs and systematic reviews are supported. We recommend evaluation and exploration of the classifications and definitions of treatment components used within this review, before future updates of this review are undertaken. Furthermore, we recommend that future research explores physical rehabilitation in relation to, and in combination with, other evidence-based non-physical interventions, such as medical and drug interventions (e.g. thrombolysis, Traditional Chinese Medicine, transcranial magnetic stimulation (TMS)). Studies emerging from China have demonstrated the ability to include relatively large numbers of participants, and lessons should be learnt from these large clinical trials.

This review synthesises the evidence in relation to function and mobility after stroke. Research is needed to consider the full range of outcomes that may be associated with improved function and mobility. These outcomes include the clinical and cost benefits potentially associated with a reduction in falls or emergency hospital admissions, and the impact of community and social care teams and services. All benefits in relation to stroke survivor-perceived quality of life, psychological mood, social participation, return to work and carer strain and well-being should be considered. This review found that many RCTs did not assess long-term follow-up, and it is essential that future RCTs plan follow-up assessments as a key feature of their design. Adequate resources should be sought to ensure that follow-up assessments are possible. The observed reduction in effect size in the available follow-up data supports research that explores additional or longer-term physiotherapy or both. Furthermore, future research should consider the long-term benefits of physical rehabilitation interventions and should explore the effects of follow-up physiotherapy assessment, self-management and treatment in maintaining benefits and preventing deterioration. Self-referral systems that will enable stroke survivors to gain follow-up physiotherapy when they believe it is necessary should also be explored.

Improvement in the reporting of RCTs of physical rehabilitation interventions is urgently needed, and we urge researchers to follow the CONSORT guidelines for reporting of clinical trials (Schulz 2010). A wide variety of outcome measures are used to assess the effects of physical rehabilitation, and we recommend research that leads to consensus and standardisation of some core outcome measures for use within future RCTs. We urge researchers to follow the guidance offered by the COMET Initiative relating to the development and reporting of core outcomes.

A stakeholder group was central to this review update, and this update has demonstrated that user involvement in Cochrane reviews is feasible and valued and can significantly impact the review structure and methods. We recommend similar models of user involvement within other Cochrane reviews and evidence syntheses.

ACKNOWLEDGEMENTS

Current versions of this review

1. Scottish Government's Chief Scientist Office, for providing funding to support this review update.

2. Hazel Fraser, Cochrane Stroke Group Managing Editor, for continued support.

3. Brenda Thomas, Cochrane Stroke Group Trials Search Coordinator, for continued support in running searches and obtaining some of the trials.

4. Trialists who responded to emails and provided various additional details about their studies: Ayse Karaduman.

5. Ashma Krishan, Cochrane Stroke Group Statistician, for responding to queries and providing help relating to metaanalyses.

6. Tom Crocker and Jaime Smith, Academic Unit of Elderly Care and Rehabilitation, University of Leeds, for assisting with the process of identification of treatment components, and providing us with feedback on their experiences of similar projects.

7. Charles Lai and Philip Chan, Hong Kong Hospital Authority, for providing advice relating to physiotherapy practice in Hong Kong and China.

8. Ming Liu for supplying us with a copy of the Chinese Stroke Rehabiliation Guidelines.

9. Julie Bernhardt for replying to queries in relation to her systematic review relating to stroke rehabilitation in China (Zhang 2013).

10. Sandra Paget, Consumer Reviewer, for providing comments on the review.

Stakeholder group

The stakeholder group was formed specifically to support the current update of this review. The broad aims of the group were to (1) ensure that the review was clinically relevant; (2) reach consensus on decisions surrounding the incorporation of Chinese studies into the previous Western classification of rehabilitation approaches and (3) guide dissemination to ensure that the updated review impacts on practice. The stakeholder group met for three halfdays throughout the period of this review update and responded to email requests in addition to this. The input of the stakeholder group was highly valuable and had considerable impact on this

review update, in particular, regarding (1) decisions around updating the way of classifying rehabilitation approaches, and incorporating non-Western approaches, within the review, (2) development of the classification system and definitions of individual treatment components, (3) selection of items for subgroup analysis and (4) interpretation of the results and assessment of implications for clinical practice and future research. All 13 members of the stakeholder group made enthusiastic and effective contributions to this review. These members included:

1. Carolyn Agnew, Lead Physiotherapist, Fife Rehabilitation Service;

2. Mrs Caroline Arhard, BSc (Hons) Physiotherapy, Stroke Specialist Physiotherapist in acute stroke, The Rehabilitation and Assessment Directorate, NHS Greater Glasgow and Clyde;

3. Jacqueline Boyle, BSc (Hons), Physiotherapist;

4. Audrey Campbell, Stroke Rehabilitation Physiotherapist, Douglas Grant Rehabilitation Centre, NHS Ayrshire and Arran;

5. Mrs Heather Goodare, MA (Oxon) Dip Couns (Brighton), consumer peer reviewer for The Cochrane Collaboration, carer for a stroke survivor;

6. Wendy Juner, Team Lead Physiotherapist, NHS Lothian;

7. Jill Skelly, Senior Physiotherapist, NHS Tayside;

8. Mark Smith, Grad Dip Phys, BSc (Hons), MPhil, MCSP; Consultant Physiotherapist NHS Lothian; visiting lecturer at Queen Margaret University, University of Glasgow and Robert Gordon's University; member of the National Advisory Committee for Stroke and the Scotland Committee of the Stroke Association; and

9. A further five members who have chosen to remain anonymous.

Previous versions of this review

1. Chest Heart and Stroke Scotland, for funding the STEP project, which made the first version of this review possible.

2. The Big Lottery Fund for current funding of the STEP project.

3. Brenda Thomas, Cochrane Stroke Group Trials Search Coordinator, for help in writing the search strategy, running the searches and obtaining some of the trials.

4. Lynsey Smyth, STEP, for help with obtaining trials and tracking down references and authors.

5. The trialists who responded to emails and provided various additional details about their studies: Cath Dean, John Green, Stefan Hesse, Susan Hillier, Tracey Howe, Ayse Karaduman, Nadina Lincoln, Nancy Mayo, Carol Richards, Nancy Salbach, Judith Salter, Joni Stoker-Yates, Paulette van Vliet, Bob Wellmon, Guo-rong Wei and Sharon Wood-Dauphinee.

6. Dr You Hong, who translated sections of Chinese trials.

7. Janet Carr and Roberta Shepherd, who sent us detailed comments on the published protocol.

CHARACTERISTICS OF STUDIES

Characteristics of included studies [ordered by study ID]

Aksu 2001

Methods	Study design: RCT with three treatment groups Method of randomisation: not stated ("Patients were randomly divided into three groups")		
Participants	Number of participants: n = 20 Inclusion criteria: "patients, whose functional levels were similar, were included"		
Interventions	The individual components deliv components, this intervention is ca Length of intervention period: not Number of sessions and length of Intervention provider: not stated (2) Group 2 (n = 7) "Six exercises were chosen from The individual components deliv components, this intervention is ca Length of intervention period: not Number of sessions and length of Intervention provider: not stated (3) Group 3 (n = 4) "Eight exercises were chosen fro The individual components deliv components, this intervention is ca Length of intervention period: not Number of sessions and length of Intervention provider: not stated This study is classified as active intervention	 (1) Group 1 (n = 9) "Four exercises were chosen from Bobath's neurodevelopmental approach" The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as a neurophysiological intervention Length of intervention period: not stated Number of sessions and length of individual sessions: not stated Intervention provider: not stated (2) Group 2 (n = 7) "Six exercises were chosen from Bobath's neurodevelopmental approach" The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as a neurophysiological intervention Length of intervention period: not stated Number of sessions and length of individual sessions: not stated Intervention period: not stated Number of sessions and length of individual sessions: not stated Intervention provider: not stated (3) Group 3 (n = 4) "Eight exercises were chosen from Bobath's neurodevelopmental approach" The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as a neurophysiological intervention Length of intervention period: not stated (3) Group 3 (n = 4) "Eight exercises were chosen from Bobath's neurodevelopmental approach" The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as a neurophysiological intervention Length of intervention is categorised as a neurophysiological intervention 	
Outcomes	Other secondary outcome measures: Stroke Rehabilitation Assessment of Movement (STREAM) Time points when outcomes were assessed: "after the stroke in the first week, motor assessment was performed"		
Notes	Abstract only No data available for analysis		
Risk of bias			

Aksu 2001 (Continued)

Random sequence generation (selection bias)	Unclear risk	No information provided
Allocation concealment (selection bias)	Unclear risk	No information provided
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	No information provided
Incomplete outcome data (attrition bias) All outcomes	Low risk	No dropouts
Free of systematic differences in baseline characteristics of groups compared?	Unclear risk	No information provided
Did authors adjust for baseline differences in their analyses?	Unclear risk	No information provided
Other bias	Unclear risk	Limited information: abstract only

Allison 2007

Methods	Study design: RCT Method of randomisation: "Randomization was achieved via the use of 20 sealed en- velopes, 10 of each containing a specific group allocation. A staff member who was blind to the study selected a sealed envelope for each participant, indicating the group alloca- tion"
Participants	Number of participants: n = 17 Inclusion criteria: "Patients with a confirmed diagnosis of recent stroke were eligible for inclusion" Exclusion criteria: terminally ill, suffering from an unstable co-morbidity and unable to participate safely (physically or mentally) in additional sessions of standing
Interventions	 (1) Intervention group (n = 7) "The second treatment group (intervention group) received the conventional treatment session, and in addition had a further session of 45 minutes standing practice on each working day. This was provided by a physiotherapy assistant and typically involved the use of either standing frames, tilt tables or standing at tables to provide support while enabling standing to occur" "Participants progressed to standing by a table for support or free standing during rehabilitation as able. Participants were encouraged to be active whilst standing-practising reaching tasks, sit-to-stand movements and so on, and were given rest periods as necessary throughout the 45-minute session. It was not possible for the physiotherapists providing the conventional treatment to be blind to the extra intervention occurring, due to the organization of therapy on the ward. This treatment regime was continued throughout the participant's stay in the rehabilitation unit. After discharge from the unit the participant was referred for outpatient or community-based physiotherapy. Intensity

bias)

a specific group allocation"

20 sealed envelopes, 10 of each containing

Allison 2007 (Continued)

Allocation concealment (selection bias)	Low risk	"A staff member who was blind to the study selected a sealed envelope for each partici- pant, indicating the group allocation"
Blinding of outcome assessment (detection bias) All outcomes	Low risk	"The measurements were conducted by a staff member who did not work on the unit, and who was blind to the treatment alloca- tion"
Incomplete outcome data (attrition bias) All outcomes	High risk	"Three of the participants allocated to the additional practice group withdrew from the additional treatment within the first week of the study, all of them citing fatigue as the reason they would not continue. One of these consented to further measures be- ing taken but two withdrew totally from the study. Results were analysed on an in- tention to treat basis, but the two partici- pants who only completed the first week of measures were excluded"
Free of systematic differences in baseline characteristics of groups compared?	Unclear risk	Limited demographic data available at baseline
Did authors adjust for baseline differences in their analyses?	Unclear risk	No information provided
Other bias	High risk	"It was not possible for the physiotherapists providing the conventional treatment to be blind to the extra intervention occurring, due to the organization of therapy on the ward." "Fatigue may be a significant bar- rier to participate in more intensive pro- grammes"

Baer 2007

Methods	Study design: single-blind RCT Method of randomisation: not stated ("subjects were randomly allocated to one of three groups")
Participants	Number of participants: n = 64 Inclusion criteria: not stated
Interventions	 (1) Part practice group (n = not stated) Participants in the part practice group were taught "part practice exercises targeted at mobility and lower limb function" The individual components delivered are listed in Table 3. Based on the individual

	components, this intervention is categorised as comprising functional task training
	Length of intervention period: four weeks
	Number of sessions and length of individual sessions: total number of sessions: three,
	but the length of individual sessions was not stated
	Intervention provider: research physiotherapist
	(2) Whole practice group (n = not stated)
	Participants in the whole practice group were taught "whole practice exercises targeted
	at mobility and lower limb function"
	The individual components delivered are listed in Table 3. Based on the individual
	components, this intervention is categorised as comprising functional task training
	Length of intervention period: four weeks
	Number of sessions and length of individual sessions: total number of sessions: three,
	but the length of individual sessions was not stated
	Intervention provider: research physiotherapist
	(3) Control group (n = not stated)
	Participants in the control group were "given information about stroke"
	The individual components delivered are listed in Table 3. Based on the individual
	components, this intervention is categorised as no intervention
	Length of intervention period: four weeks
	Number of sessions and length of individual sessions: total number of sessions: three,
	but the length of individual sessions was not stated
	Intervention provider: research physiotherapist
	This study is classified as active intervention one (functional task training) versus active
	intervention two (functional task training) (Table 6) versus no treatment (Table 4)
Outcomes	Measures of motor function: Motor Assessment Scale
outcomes	Measures of postural control and balance: Timed Up and Go over two metres (TUG2m)
	, Step test
	Measures of voluntary movements: gait speed
	Time points when outcomes were assessed: "Baseline outcome measures were taken on
	two occasions prior to the intervention phase and meaned (base). The baseline was
	compared to outcomes taken at the end of intervention (OM3) and a 48 hour retention
	test (OM4)"
Notes	Abstract only-research report platform presentation
	No suitable data available for analysis
	,
Risk of bias	

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	No information provided
Allocation concealment (selection bias)	Low risk	Reported as a single-blind RCT
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	No information provided

Incomplete outcome data (attrition bias) All outcomes	Unclear risk	No information provided
Free of systematic differences in baseline characteristics of groups compared?	Unclear risk	No information provided about the indi- vidual groups
Did authors adjust for baseline differences in their analyses?	Unclear risk	No information provided about the indi- vidual groups
Other bias	Unclear risk	Limited information-abstract only
Bai 2008		
Methods	Study design: RCT Method of randomisation: not stated ("patients were randomized into two treatment groups")	
Participants	Number of participants: n = 364 Inclusion criteria: "admission[s] were stabilized within one week of symptoms, Glasgow Coma Scale (GCS) score > 8, limb disability, aged between 40 years and 80 years" Exclusion criteria: "cerebrovascular disease history with residual symptoms, onset of ICH more than three weeks prior, tetraplegia, history of dementia and not resident locally"	
Interventions	Exclusion criteria: "cerebrovascular disease history with residual symptoms, onset of ICH	

	 therapists who directed their training every two weekstreatment was conducted by one therapist per patient" (2) Control group (n = 181) "Routine internal medical intervention" The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as no intervention Length of intervention period: no intervention Number of sessions and length of individual sessions: no intervention Intervention provider: no intervention This study is classified as intervention (functional task training) versus no treatment (Table 4)
Outcomes	Measures of independence in ADL: modified Barthel Index Measures of motor function: Fugl-Meyer Assessment Time points when outcomes were assessed: "were administered at various times, including at admission and at one, three, and six months after the stroke"
Notes	No outcomes included in analysis (data shown in graphical representation only and SD not reported). Clarification of data sought but not obtained

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	No information provided
Allocation concealment (selection bias)	Unclear risk	No information provided
Blinding of outcome assessment (detection bias) All outcomes	Low risk	"All measurements were recorded by an as- sessor who was blinded to the study design and details" "If the assessments took place when the pa- tients were still hospitalized, trial staff were informed of an impending assessor visit so that the assessor, who was blinded to study design, would not inadvertently view a re- habilitation session"
Incomplete outcome data (attrition bias) All outcomes	Low risk	"Six months after the stroke, 12 patients (four in the rehabilitation group and eight in the control group) were lost to follow- up, and seven patients (two in the rehabili- tation group and five in the control group) died" (relatively low numbers lost to follow- up in relation to participant size of 364)
Free of systematic differences in baseline characteristics of groups compared?	Low risk	"On admission, the rehabilitation group and the control group were comparable on all baseline measures"

Bai 2008 (Continued)

Did authors adjust for baseline differences in their analyses?	Low risk	No information provided
Other bias	Unclear risk	No information provided
Bale 2008		
Methods	Study design: RCT Method of randomisation: "Patients who volunteered and gave written informed consent were randomly allocated to two different training groups, either a functional strength training group or a training-as-usual group by drawing lots. From a total number of 20, 10 were allotted to each training group"	
Participants	Number of participants: n = 18 Inclusion criteria: first onset of stroke with reduced muscle strength in the affected leg, ability to understand verbal information, able to sit without support Exclusion criteria: significant sensory or cognitive sequelae, arrhythmia, uncontrolled angina pectoris or hypertension or co-morbidities that could mask the sequelae from the stroke and patients with no motor control of the affected leg	
Interventions		

Bale 2008 (Continued)

	3 of each patient's training period to obtain information about attendance and quantity of training in the wards, and in sessions with occupational therapists" The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising functional task training and neurophysiological intervention Length of intervention period: four weeks Number of sessions and length of individual sessions: 50 minutes/d five days a week Intervention provider: Different physiotherapists trained participants in the two inter- vention groups This study is classified as active intervention one (functional task training, musculoskele- tal (active)) versus active intervention two (functional task training, neurophysiological) (Table 6)
Outcomes	Measures of motor function: Motor Assessment Scale Measures of voluntary movement: gait speed over 12 metres Measures of muscle strength: dynamometer measures of knee extension and flexion Other secondary outcome measures: maximum weight bearing, Patient Global Impres- sion of Change Time points when outcomes were assessed: at inclusion and after four weeks
N	

Notes

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	"Randomly allocated to two different train- ing groups, either a functional strength training group or a training-as-usual group by drawing lots"
Allocation concealment (selection bias)	Unclear risk	Not enough information provided
Blinding of outcome assessment (detection bias) All outcomes	Low risk	"Two physiotherapists performed the phys- ical measurements, and were blinded to the patients' group assignment. Before the study started, the testers were trained to perform the measurements based on a test protocol. To improve reliability they tested four patients independently at the same time, and discussed their scores afterwards"
Incomplete outcome data (attrition bias) All outcomes	Low risk	No dropouts
Free of systematic differences in baseline characteristics of groups compared?	Low risk	"At inclusion there were no statistical sig- nificant differences between the groups, neither in demographic variables nor in physical performance measures"

Bale 2008 (Continued)

Did authors adjust for baseline differences in their analyses?	Low risk	No information provided
Other bias	Unclear risk	No information provided
Behrman 2011		
Methods	Study design: single-blind RCT Method of randomisation: not stated	
Participants	Number of participants: n = 408 Inclusion criteria: "We compared the effect of two interventions to usual care initiated at two months and assessed at 6 months post-stroke in 408 adults stratified by walking impairment (severe, < 0.4 m/s; moderate, 0.4-0.79 m/s)"	
Interventions	Inclusion criteria: "We compared the effect of two interventions to usual care initiated at two months and assessed at 6 months post-stroke in 408 adults stratified by walking	
Outcomes	Measures of voluntary movements: the proportion of participants that transitioned to a higher functional walking level six months post stroke, walking speed and distance Measures of postural control and balance: daily step number Measures of participation: functional status (specific scale not stated)	

Behrman 2011 (Continued)

	Measures of quality of life and social isolation: quality of life (specific scale not stated) Time points when outcomes were assessed: six months post stroke
Notes	Abstract only Locomotor training programme (group one) intervention includes treadmill training as key intervention and therefore is not relevant to this study

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	No information provided
Allocation concealment (selection bias)	Unclear risk	No information provided
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	No information provided
Incomplete outcome data (attrition bias) All outcomes	Unclear risk	Insufficent information provided
Free of systematic differences in baseline characteristics of groups compared?	Unclear risk	Baseline characteristics not reported
Did authors adjust for baseline differences in their analyses?	Unclear risk	Not applicable
Other bias	Unclear risk	Limited information available-abstract only

Blennerhassett 2004

Methods	Study design: prospective single-blind RCT Method of randomisation: "Subjects were assigned randomly to either an Upper Limb or Mobility training group. Randomisation was performed by a person independent from the study drawing a pre-sealed opaque envelope that specified group allocation"
Participants	Number of participants: n = 30 Inclusion criteria: "The selection criteria were the ability to walk 10 metres with close supervision (with or without walking aids) and ability to provide informed consent" Exclusion criteria: "Deteriorating medical condition, or if they were independent com- munity ambulators"
Interventions	(1) Mobility group (n = 15)"In addition to the study intervention, all subjects received their usual interdisciplinary rehabilitation, which included one hour of physiotherapy, five days a week. This phys-

iotherapy was based predominantly upon the Movement Science approach (Carr 2002) . The duration of interdisciplinary therapy was recorded"

"Both the Mobility and Upper Limb Groups received additional task-related practice for one hour a day, five days per week for four weeks. After the four weeks training, participants ceased the additional practice and continued with their interdisciplinary rehabilitation program. Each session consisted of a circuit of 10 five-minute workstations, with up to four subjects in each session. A physiotherapy department staff member supervised all sessions closely, and all activities were customised and progressed to suit individual subjects"

Mobility circuit classes were conducted separately from the upper limb sessions

"Mobility Group activities included warm-up and endurance tasks using stationary bikes and treadmills, followed by functional tasks such as sit to stand, step-ups, obstacle course walking, standing balance, stretching as required, and strengthening using traditional gymnasium equipment"

The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising cardiopulmonary intervention, functional task training and musculoskeletal intervention (active)

Length of intervention period: four weeks

Number of sessions and length of individual sessions: "Usual interdisciplinary rehabilitation, which included one hour of physiotherapy, five days a week. Additional taskrelated practice for one hour a day, five days per week"

Intervention provider: physiotherapists

(2) Upper limb group (n = 15)

"Upper Limb Group activities commenced with a warm-up (arm ergometer) followed by functional tasks to improve reach and grasp, hand-eye coordination activities, stretching as required, and strengthening using traditional gymnasium equipment. Therapistassisted exercises were incorporated for subjects with limited control of arm or hand movement"

The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising upper limb training Length of intervention period: four weeks

Number of sessions and length of individual sessions: "Usual interdisciplinary rehabilitation, which included one hour of physiotherapy, five days a week. Additional taskrelated practice for one hour a day, five days per week"

Intervention provider: physiotherapists This study is classified as intervention (functional task training and musculoskeletal intervention (active)) versus attention control (upper limb training) (Table 5). The intervention group also received cardiopulmonary intervention

Time points when outcomes were assessed: "Measures of both mobility and upper limb function were performed on three occasions: (1) prior to commencement in the trial, (2) immediately after the 4-week additional training, and (3) at follow-up six months

Measures of motor function: Motor Assessment Scale (upper arm and hand) Measures of postural control and balance: Timed Up and Go test, Step test

Other secondary outcome measures: Jebsen Taylor Hand Function Test

Measures of voluntary movements: Six-Minute Walk test

after completing the additional training"

Outcomes

Notes

Risk of bias

Risk of bias		
Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	"Randomisation was performed by a per- son independent from the study drawing a pre-sealed opaque envelope that specified group allocation"
Allocation concealment (selection bias)	Unclear risk	"Subjects were not blinded to the research procedure although they were not told of the study hypotheses. Treating physiother- apists were not told of group allocations al- though they may have found out through interaction with subjects during physio- therapy treatments"
Blinding of outcome assessment (detection bias) All outcomes	Low risk	"An independent assessor who was blinded to group allocation and previous test re- sults, and was not involved in the treatment of the subject, performed all tests"
Incomplete outcome data (attrition bias) All outcomes	Low risk	Dropouts accounted for: "All subjects com- pleted four weeks of additional training and follow-up was 100% at four weeks and 97% at six months. All subjects completed the mobility and MAS measurements on the initial and four week test. There were data missing from the JTHFT. At the four week assessment only 12 subjects from each group were able to perform the JTHFT. Of these subjects, the Mobility Group had six left and six right side affected, and the Upper Limb Group had seven left and five right side affected. One subject from the Upper Limb Group was not tested at the six month follow-up as he sustained a hip fracture secondary to a fall after discharge"
Free of systematic differences in baseline characteristics of groups compared?	Low risk	"The groups were comparable at com- mencement of the study for factors such as age, gender, type of stroke, side affected, time from stroke onset to rehabilitation ad- mission, or time between onset and com- mencing the study ($p = 0.52$ to 1.00) (see Tables 1 and 2)"

Did authors adjust for baseline differences in their analyses?	Low risk	No information provided
Other bias	Unclear risk	"The number of additional practice ses- sions attended and total duration of in- terdisciplinary therapy were similar for the two groups ($p = 0.57$ to 0.87). In addition, no difference was found between groups for the duration of mobility and upper limb related practice delivered within the usual physiotherapy sessions ($p = 0.35$ to 0.60)"

Brock 2005

Methods	Study design: multi-centre RCT Method of randomisation: "Randomization was done through a computer-generated, stratified, blocked randomization procedure. Patients were stratified according to time period from date of stroke to date of commencement in the trial. The two strata were four weeks to eight weeks post-stroke at commencement of the trial and more than eight weeks post-stroke. This stratification aimed to improve the likelihood of the two groups being similar in terms of initial severity and speed of recovery post-stroke, as those with milder stroke and a quicker rate of recovery are likely to improve more rapidly during the time period of the study. Separate computer-generated randomizations were used for each site. Opaque envelopes were used to conceal group allocation. Participants were randomized and assigned to the intervention groups after the baseline assessments were carried out"
Participants	Number of participants: n = 26 Inclusion criteria: "first or recurrent stroke, haemorrhage or infarct, between four weeks and 20 weeks post-stroke at commencement of trial, currently participating in an inpa- tient or outpatient rehabilitation programme and able to walk 15 metres indoors on a level surface, with or without an aid, with supervision" Exclusion criteria: "independent mobility indoors achieved within four weeks post- stroke, premorbid mobility limited to walking indoors only, unable to follow single stage verbal commands with visual prompts and mobility disability due primarily to patholo- gies other than stroke"
Interventions	(1) Bobath intervention (n = 12) "Intervention A was based on the Bobath concept. In this intervention, participants received individual treatment prescription based on the Bobath concept towards the goal of improving walking ability in different environmental contexts. This interven- tion included detailed assessment of the individual's movement strategies and the neuro- logical and neuromuscular deficits underlying motor dysfunction. Treatment strategies were individualized and aimed at both reducing the severity of impairments where they impacted on function, and optimizing postural and movement strategies to improve efficiency and maximize function" "The specific goal of therapy in this study was to improve the ability of the participant to walk safely in different environments, including components of endurance, walking

on slopes, going up and down a single step and walking over rough ground. The session incorporated structured task practice (as described in intervention B) for 1/6 of the treatment time allocated"

The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising cardiopulmonary intervention, functional task training and neurophysiological intervention

Length of intervention period: two weeks

Number of sessions and length of individual sessions: "Participants in both groups received six one hour physiotherapy sessions over a two-week period. During the intervention period, participants did not receive any other physiotherapy aimed at improving mobility, posture, balance or lower limb function. Instead, the intervention sessions replaced the usual physiotherapy treatment for mobility. Additional physiotherapy was provided in sitting or lying for other rehabilitation goals, such as independence in bed mobility and recovery of upper limb function"

Intervention provider: "Both interventions were performed by physiotherapists with at least five years' postgraduate experience and at least two years' experience in the fields of rehabilitation or neurology. In addition, therapists providing Intervention A had to have also completed a Basic Bobath Course and at least two Advanced Bobath Courses (a minimum of 180 hours of formal training acquired over a minimum of three years)" (2) Task practice intervention (n = 14)

"Participants receiving Intervention B undertook physiotherapy based on structured task practice. The supervised exercise programme aimed to provide repeated task specific practice of environmental contexts frequently encountered in walking outdoors. The tasks practised focused on increasing endurance, walking on slopes, going up and down a single step and walking over rough ground. Based on principles of motor learning, the therapist provided instruction in how to perform the task, including demonstration, verbal cueing to correct ineffective adaptive motor patterns and feedback on the performance of the task as specified by the study protocol, as well as supervision for safety. The therapist did not provide hands-on assistance or guidance during tasks. Half of the task practice component was conducted as repetitive practice using standardized equipment in the gymnasium, reflecting the closed skill stage of learning. The other half of the time was spent in environments outside the gymnasium, walking on varying surfaces indoors and outdoors, bringing in other environmental contexts, such as differing attentional demands and changes in direction"

The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising cardiopulmonary intervention and functional task training

Length of intervention period: two weeks

Number of sessions and length of individual sessions: "Participants in both groups received six one hour physiotherapy sessions over a two-week period"

Intervention provider: "Physiotherapists with at least five years' postgraduate experience and at least two years' experience in the fields of rehabilitation or neurology"

This study was classified as: active intervention one (functional task training, neurophysiological) versus active intervention two (functional task training) (Table 6). Both intervention groups also received cardiopulmonary intervention

Outcomes

Measures of postural control and balance: Berg Balance Scale Measures of voluntary movements: adapted Six-Minute Walk test, gait velocity Time points when outcomes were assessed: "Measures were taken at baseline, and fol-

Brock 2005 (Continued)

lowing treatment...Post-intervention assessment measures were recorded between one and five days following the intervention"

Notes

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	"Randomization was done through a com- puter-generated, stratified, blocked ran- domization procedure. Separate computer- generated randomizations were used for each site. Opaque envelopes were used to conceal group allocation. Participants were randomized and assigned to the interven- tion groups after the baseline assessments were carried out"
Allocation concealment (selection bias)	Low risk	"Patients were stratified according to time period from date of stroke to date of com- mencement in the trial. The two strata were four weeks to eight weeks post-stroke at commencement of the trial and more than eight weeks post-stroke. This stratifi- cation aimed to improve the likelihood of the two groups being similar in terms of initial severity and speed of recovery post- stroke, as those with milder stroke and a quicker rate of recovery are likely to im- prove more rapidly during the time period of the study"
Blinding of outcome assessment (detection bias) All outcomes	Low risk	"Measures were taken at baseline, and fol- lowing treatment, by a physiotherapist who was blind to group assignment"
Incomplete outcome data (attrition bias) All outcomes	Unclear risk	"Twenty-nine participants were recruited to the study. Note that two participants did not complete the study because they were discharged from inpatient rehabilita- tion earlier than anticipated and could not complete the study as outpatients. One par- ticipant was withdrawn due to ill health" Both of the early discharges were in the same (Bobath) group. Intention-to-treat analysis not completed-unclear whether these dropouts could contribute to attrition bias

Free of systematic differences in baseline characteristics of groups compared?	Low risk	"No significant differences between groups at baseline for the six minute walk test (P = 0.79), gait velocity (P = 0.27) and Berg Balance Scale (P = 0.77)"
Did authors adjust for baseline differences in their analyses?	Low risk	No information provided
Other bias	Unclear risk	"No data are available regarding the num- ber of patients eligible to participate or rea- sons for not participating. However, for both centres, the main limiting factor to re- cruitment was planned discharge to a dis- tant locality shortly after achieving walking with supervision, preventing participation"

Carlson 2006

Methods	Study design: RCT Method of randomisation: not stated ("Subjects were randomised into treatment (n = 6) and control (n = 5) groups")
Participants	Number of participants: n = 11 Inclusion criteria: not stated ("Eleven subjects with hemiparesisparticipated in this study")
Interventions	 (1) Treatment group (n = 6) "received intense massed practice with interventions focused on forcing use of the affected lower extremity" The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as functional task training Length of intervention period: two weeks Number of sessions and length of individual sessions: three hours/d Intervention provider: not stated (2) Control group (n = 5) "Control subjects did not receive any intervention" The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as no intervention Length of intervention period: no intervention Intervention provider: no intervention The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as no intervention Length of intervention period: no intervention Intervention provider: no intervention Intervention provider: no intervention The individual components delivered in table 3. Based on the individual components, this intervention is categorised as no intervention Length of intervention period: no intervention Intervention provider: no intervention The individual sessions: no intervention This study is classified as intervention (functional task training) versus no treatment (Table 4)
Outcomes	Measures of postural control and balance: Berg Balance Scale Measures of voluntary movements: self-selected gait speed Other secondary outcome measures: weight-bearing ratios in quiet standing and weight- bearing ratios during ambulation

Carlson 2006 (Continued)

	Time points when outcomes were assessed: "testing was performed at pre-test, post-test, and again at 3-month follow-up"
Notes	Abstract only No data suitable for analysis

Incomplete outcome data (attrition bias) All outcomes	Unclear risk	Insufficient information available
Free of systematic differences in baseline characteristics of groups compared?	Unclear risk	No information provided
Did authors adjust for baseline differences in their analyses?	Unclear risk	No information provided
Other bias	Unclear risk	Limited information available

Chan 2006

Methods	Study design: matched-pair RCT Method of randomisation: "Random assignment of patients into the sequential func- tion-based motor relearning group and the conventional therapy (control) group wa conducted in two stages. The first stage involved arranging patients into a block of si participants and then forming the six into pairs by matching their age and gender; ther if possible, they were matched according to the level of intensity of physiotherapy an speech therapy received in the hospital. Patients who did not form a best-matched pair were automatically entered into the next block for further matching and randomization The patients were excluded from the study if their characteristics were not matched b the end of the second round. The second stage involved randomly assigning the tw patients in each of the best-matched pairs to either the motor relearning or the control groups by drawing one of two sealed envelopes designating the group membership"	
Participants	Number of participants: n = 66 Inclusion criteria: "patients had to be between 21 and 65 years of age (eligible admission to outpatient setting), diagnosed as having suffered a first stroke, the stroke must have	

	occurred within the previous 12 months, and patients had to be able to follow simple instructions as screened by the Chinese version of the Cognistat" Exclusion criteria: "conditions were complicated by other musculoskeletal injuries and/ or visual deficits"
Interventions	 (1) Motor relearning group (n = 33) "Both programmes were conducted in the same treatment area located in the occupational therapy department of the hospital. The patients in both programmes also received physical therapy in the form of lower limb strengthening and trunk balance exercises. The patients attended physical therapy from one to three times a week. Their attendance was monitored throughout the study, and the number of sessions was incorporated into the analysis of the results" "In the motor relearning programme, the intervention technique followed four sequential steps: identification of the missing performance components (step 1), training using remedial exercises (step 2), training using functional task components (step 3), and transfer of skills to functional tasks performance (step 4). A total of 24 remedial tasks (used in step 2) and 10 functional tasks (used in step 4) were designed to cover deficits in static and dynamic sitting balance, and static and dynamic standing balance. Throughout the training session, the therapist stressed the importance of relating the training processes taking place in steps 2 and 3 to practices in step 4. The training progressed by advancing from a sitting to a standing position, and from static to dynamic balancing. The criteria established for progression were clearly defined, and those patients who demonstrated the desirable skills were upgraded to another stage of training" The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as functional task training Length of intervention period: six weeks Number of sessions and length of individual sessions: three two-hour sessions each week (18 sessions total) Intervention provider: occupational therapist: "The researcher conducted the motor
	 relearning programme" (2) Conventional therapy group (n = 33) "The skill training method was adopted for use with patients receiving the conventional therapy programme. The same number of remedial and functional tasks was covered as in the motor relearning programme. The selection of remedial tasks followed the principle of progressing from a sitting to a standing position, and from static to dynamic balance. The training of functional tasks began with simple self-care and bedside tasks, such as bed mobility, and progressed to more complicated tasks, such as use of community facilities. Unlike the motor relearning programme, the patients were not involved in identifying their own missing performance components (Table 2). The relationships between the practices of the remedial tasks and the entire functional task performance were not reinforced" The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as functional task training Length of intervention period: six weeks Number of sessions and length of individual sessions: three two-hour sessions each week (18 sessions total) Intervention provider: "another occupational therapist conducted the conventional therapy programme. The therapist responsible for the conventional therapy programme was trained in the standardized procedure for conducting the control programme"

Chan 2006 (Continued)

	This study is classified as active intervention one (functional task training) versus active intervention two (functional task training) (Table 6)
Outcomes	Measures of independence in ADL: Functional Independence Measure Measures of postural control and balance: Berg Balance Scale, Timed Up and Go test Measures of participation: instrumental ADL Measures of quality of life and social isolation: Community Integration Questionnaire Time points when outcomes were assessed: "The assessment schedule was laid out at baseline (after randomization), two weeks, four weeks, and six weeks"
Notes	The two active interventions appear fairly similar. As the two active treatment groups were classified as including similar treatment components, data from this study have not been included within the comparisons of one active intervention versus another active intervention

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	High risk	"Random assignment of patients into the sequential function-based motor relearning group and the conventional therapy (control) group was conducted in two stages. The first stage involved arranging patients into a block of six participants and then forming the six into pairs by matching their age and gender; then, if possible, they were matched according to the level of intensity of physiotherapy and speech therapy received in the hospital. Patients who did not form a best-matched pair were automatically entered into the next block for further matching and randomization. The patients were excluded from the study if their characteristics were not matched by the end of the second round. The second stage involved randomly assigning the two patients in each of the best-matched pairs to either the motor relearning or the control groups by drawing one of two sealed envelopes designating the group membership"

Chan 2006 (Continued)

		troduce biases into the selection of patients to participate in the study"
Allocation concealment (selection bias)	Low risk	"The randomization process was carried out by a registration clerk who was not in- volved in any part of the study"
Blinding of outcome assessment (detection bias) All outcomes	Low risk	"All the clinical outcome assessments were conducted by two occupational therapists who were working in the orthopaedic unit of the same outpatient centre. The asses- sors were blind to the group membership of the patients they assessed. Training sessions were provided to all raters on administering and scoring each clinical instrument in or- der to minimize any biases associated with the assessment process"
Incomplete outcome data (attrition bias) All outcomes	High risk	In the motor relearning group, seven par- ticipants discontinued the intervention for the following reasons: "suspended treat- ment due to travelling for more than two weeks (n = 2); re-admitted to hospital due to medical problem (n = 1); excluded from analysis due to the drop-out of matched counterpart in conventional therapy group (n = 4)" In the conventional therapy group, seven participants discontinued the intervention for the following reasons: "suspended due to irregular attendance (n = 1); re-admitted to hospital due to medical problem (n = 1); defaulted treatment (n = 2); excluded from analysis due [to] drop-out of matched counterpart in motor relearning group (n = 3)" Judged at high risk as the result of exclu- sion of participants because their "matched counterpart" dropped out
Free of systematic differences in baseline characteristics of groups compared?	Low risk	"There were no significant differences in the demographic and medical character- istics of the patients between the motor relearning and control groups. Also, no significant differences were found in their scores on the five outcome measures at the baseline"

Did authors adjust for baseline differences in their analyses?	Low risk	No information provided
Other bias	High risk	Judged at high risk, as study authors state: "Although the assessors were blind to the study, the motor relearning programme was conducted by the researcher, who might have provided more enthusiastic interven- tions than the therapist who conducted the control programme" Additionally, "The patients received other treatment interventions in addition to the motor relearning or control programme, such as physiotherapy and speech therapy, that could contaminate the treatment ef- fects. The patients attended the treatment sessions as day-patients, and their engage- ment in activities other than those con- ducted during treatment possibly further contaminated these effects"
Chen 2004 Methods	Study design: RCT Method of randomisation: not stated	
Participants	Number of participants: n = 78 Inclusion criteria: "Met the 1995 National stroke diagnosis guidelines, first stroke as confirmed by CT or MRI scan, persistent deficits in motor function, within three weeks after stroke, no severe conditions of the heart, liver, kidney and medically stable" Age stated in paper as "between 40-48." However, review authors have assumed that this is a typo, as mean age reported in the study is 60.95 years for the rehabilitation group and 62.36 years for the control group	
Interventions	 (1) Rehabilitation group (n = 39) "Patients in the rehabilitation group were given physical training in addition to routine treatment. The treatment group commenced daily therapy after they were medically stable. Each training session began with the therapist guiding and delivering the therapy lasting 45 min/day. Participant's family learned the exercises alongside each training session, using approximately 0.5 hour/day to consolidate and reinforce the exercises taught" The intervention mainly consisted of the following. (a) Correct positioning of limbs in bed (supine position, lateral position with affected limbs at lower side and healthy limbs at upper side and lateral position with affected limbs at upper side and healthy limbs at lower side) (b) Passive ranging exercises of all joints of the affected limbs (therapist placed one hand on the proximal joint and another hand on the distal joint to deliver gentle, slow and rhythmic movements to the joints) 	

	sion while performing ranging exercises on t skin) (d) Active ranging exercises of the affected li in carrying out active-assisted range of motio as well as active ranging exercises of all joint (e) Training in sitting balance, standing and down stair practice when possible (f) ADL training (participants actively work dressing activities); learned all possible tech pants with severe impairment to learn single vring the wheelchair The individual components delivered are lis ponents, this intervention is categorised as a loskeletal intervention (active), musculoske ological intervention Length of intervention period: not stated, be three months of therapy Number of sessions and length of individu details stated Intervention provider: therapist during tra reinforcement of exercises taught during tra (2) Control group (n = 39) "Patients in the control group received rout	ts) gait re-education, commencing up stair and ed on completing eating, washing, combing, niques to achieve the above actions, partici- t-hand and single-leg techniques of manoeu- ted in Table 3. Based on the individual com- comprising functional task training, muscu- letal intervention (passive) and neurophysi- but final outcome assessment was done after al sessions: 45 minutes per day. No further ining session. Participants' family provided uning session ine treatment" listed in Table 3. Based on the individual d as comprising no intervention al sessions: not stated onal task training, musculoskeletal interven-
Outcomes	Measures of independence in ADL: Barthel Index Time points when outcomes were assessed: "before therapy (not stated when specifically) , after 1 month of therapy, after 3 months of therapy"	
Notes	Original study translated from Chinese to English	
Risk of bias

Other bias	Unclear risk	No information provided
Chen 2006		
Methods	Study design: RCT Method of randomisation: not stated	
Participants	Number of participants: n = 45 Inclusion criteria: "stroke patients diagnosed according to the evaluative standard revised by the Fourth [National] Academic Conference of Cerebral Vascular Disease and lived in communities around the Second Hospital of Zhengzhou University from 2003 to 2005"	
Interventions	2005" (1) Rehabilitation group (n = 25) "All patients underwent the same routine medical treatment, patients from the reha- bilitation group [were] additionally treated with community-based rehabilitation for 3 months. Appropriate therapies were given after detailed examination and rehabilitation assessment, giving community-based rehabilitation training at home, giving the patient and family members comprehensive guidance, with regular follow up assessment, with all questions encountered during the rehabilitation process answered timely, and contin- uously adjusting the rehabilitation treatment according to the patient's response" Rehabilitation measures: "Treatment during the flaccid stage was on preventing joint contractures and deformity, preventing secondary complications; treatment during the spasticity stage was on controlling muscle spasticity and abnormal movements to en- courage normal movement patterns to emerge. Main content included: passive rang- ing exercises of all joints, rolling from affected and non-affected sides practice, balance ability training (including sitting and standing balance practice), transfers (bed to chair transfer, sit to stand transfer) training, gait training (ambulation, up and down stairs) and stretching in wrist extension and ankle dorsiflexion. ADL training included feeding, donning, personal hygiene management etc. At the same time, psychological recovery and social adaptation training were given, mainly on fostering good patient-doctor rela- tionships to help them build confidence, release negative emotions, guide and encourage	

Chen 2006 (Continued)

	them to express their feelings. Training was given in a way that adapted to the training environment, overcame limitation in resources through simplification, adapted to the situation and presenting condition, focused on involving the family members' partici- pation, alterations to the home environment, maximising the resources at home" The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising functional task training and musculoskeletal intervention (passive) Length of intervention period: three months Number of sessions and length of individual sessions: two/wk, no other details given Intervention provider: not stated (2) Control group (n = 20) "Routine medical treatment" The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising no intervention Length of intervention period: not stated Number of sessions and length of individual sessions: not stated Intervention period: not stated Number of sessions and length of individual sessions: not stated Intervention period: not stated
) versus no treatment (Table 4)
Outcomes	Measures of independence in ADL: Barthel Index Other secondary outcomes: Mini Mental State Examination (MMSE) Time points when outcomes were assessed: before intervention and after three months of community-based rehabilitation

Cooke 2006		
Methods	Study design: observer-blind, phase one RCT Method of randomisation: "An independent statistician produced a pretrial computer generated randomized group allocation order in blocks of 9 per trial center. Allocation was stratified by baseline scores for unilateral visual spatial neglect (Star Cancellation Test, 50-54 no spatial neglect and 0-49 unilateral spatial neglect present). Allocation was concealed in sequentially numbered sealed opaque envelopes held by an independent ad- ministrator. Envelopes were opened in response to a telephone request from the research physiotherapist (blinded to measures) after the assessor (blinded to group allocation) had completed baseline measures"	
Participants	Number of participants: n = 109 Inclusion criteria: "inpatients older than 18 years, between 1 and 13 weeks after anterior circulatory stroke (hemorrhage or infarction), some voluntary muscle contraction in the paretic lower limb (a score of at least 28/100 on the lower limb section of the motricity index), with potential for clinically important improvement was present, able to follow a 1-stage command, independently mobile (with or without aids), prior to the index stroke, no orthopedic surgery, no trauma affecting the lower limb in the last 8 weeks, and there was no previous history of neurological disease other than stroke"	
Interventions	and there was no previous history of neurological disease other than stroke" (1) Additional conventional therapy (CPT + CPT) group (n = 35) "Focused on those interventions in the treatment schedule that emphasized control/ quality of movement and gave prominence to sensory stimulation and preparation of joint and muscle alignment prior to activating muscle or a functional task. Additional CPT was therefore strongly therapist hands-on, with provision of passive movements, active assisted exercise, and/or hands-on intervention to facilitate muscle activity or functional ability. Some active exercise and repetitive practice of functional tasks [were] included but without systematic progression in resistance or repetition" The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as functional task training, musculoskele- tal intervention (active), musculoskeletal intervention (passive) and neurophysiological intervention Length of intervention period: six weeks Number of sessions and length of individual sessions: standardised treatment schedules for up to one hour, four days a week for six weeks (total = 24 hours) Intervention provider: research physiotherapists (independent of the clinical team) (2) Functional strength training (FST + CPT) group (n = 36) "Delivery of FST directed participants' attention to the exercise/activity being performed, appropriate verbal feedback on performance, and repetition (therapist hands-off). Con- tent of FST focused on repetitive, progressive resistive exercise during goal-directed func- tional activity. The emphasis was on producing appropriate muscle force for the func- tional activity being practiced. Treatment progressed systematically using repetition and	

Cooke 2006 (Continued)

	increase in resistance by, for example, changing the limb's relationship to gravity, increase ing the range of movement or distance over which bodyweight was transported, and changing the weight of external objects used to provide resistance. Treatment activities progressed systematically from light to heavy loads and from few to many repetitions. Participants performed repetitive exercise of functional tasks such as sit-to-stand-to-sit, stair climbing/step ups, inside and outside walking, transfer training, bed mobility, and treadmill training with and without the use of a bodyweight support system" The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as functional task training, musculoskeletal intervention (active) and neurophysiological intervention Length of intervention period: six weeks Number of sessions and length of individual sessions: standardised treatment schedules for up to one hour, four days a week for six weeks (total = 24 hours) Intervention provider: research physiotherapists (independent of the clinical team) (3) Conventional physiotherapy (CPT) group (n = 38) "Routine CPT included soft tissue mobilization, facilitation of muscle activity, facili- tation of coordinated multijoint movement, tactile and proprioceptive input, resistive exercise, and functional retraining" The individual components delivered are listed in Table 3. Based on the individual com- ponents, this intervention is categorised as usual care (functional task training, muscu- loskeletal intervention) Length of intervention period: six weeks Number of sessions and length of individual sessions: standardised treatment schedules for up to one hour, four days a week for six weeks (total = 24 hours) Intervention provider: research physiotherapists (independent of the clinical team) This study is classified as active Intervention one (functional task training, musculoskeletat intervention provider: research physiotherapists (independent of the clinical te
Outcomes	Measures of motor function: modified Rivermead Motor Assessment Measures of voluntary movements: 10-Metre Walk test, ability to walk at 0.8 m/s or more, temporal-spatial gait parameters (symmetry of step length and step time) Measure of muscle strength: torque around the paretic knee during concentric isokinetic extension, followed immediately by flexion (using the CYBEX NORM isokinetic dy- namometer) Measures of quality of life and social isolation: EuroQol Time points when outcomes were assessed: "Participants provided written informed consent and then completed baseline measures. Intervention began on the following day for 6 weeks. Participants repeated the measurement battery on completion of the intervention phase (outcome) and 12 weeks later (follow-up)"
Notes	As the two active treatment groups were classified as including similar treatment com- ponents, data from this study have not been included within the comparisons of one active intervention versus another active intervention

Methods	Study design: RCT Method of randomisation: blocked randomisation ("subjects drew a card from a box that was originally filled with 10 control and 10 experimental cards")
Participants	Number of participants: n = 20 Inclusion criteria: diagnosed with stroke more than one year previously, discharged from rehabilitation, able to understand instructions, able to give informed consent, no or- thopaedic problems that could interfere with ability to perform seated reaching tasks and able to sit unsupported for 20 minutes
Interventions	 (1) Motor learning group (n = 10) Standardised training programme designed to improve sitting balance through reaching with the unaffected hand "The training for the experimental group was designed to improve sitting balance and involved emphasis on appropriate loading of the affected leg while practicing reaching tasks using the unaffected hand to grasp objects located beyond arm's length. The reaching tasks using the unaffected hand to grasp objects located beyond arm's length. The reaching tasks user performed under systematically varied conditions. Distance and direction were varied by changing the location of the object. Seat height, movement speed, object weight, and extent of thigh support on the seat were also varied. The training was advanced by increasing the number of repetitions and complexity of the tasks." The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising functional task training Length of intervention period: two weeks Number of sessions and length of individual sessions: 10 sessions over two weeks, average of 30 minutes Intervention provider: "the training programs were carried out by the first author in the subject's home" (2) Placebo group (n = 10) Cognitive manipulative tasks, involving reaching the unaffected hand over very small distances "Control group had sham training that incorporated the performance of cognitive-manipulative tasks while seated at a table. Sham training was advanced over sessions by increasing the repetitions and cognitive difficulty of the tasks. The subjects in subjects in the control group performed an equal number of reaching movements as the subjects assigned to the experimental group; however, the nature of the tasks ensured that only a minimum balance perturbation occurred" The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as

	stand
	Measures of voluntary movement: timed 10-Metre Walk
	Other measures: time to complete cognitive task
	Time points when outcomes were assessed: "pretest and posttest group design was used"

Notes

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	"Subjects were randomly assigned to either the experimental or control group. Ran- domization was blocked to ensure equal numbers in the groups. The procedure in- volved random sampling without replace- ment; subjects drew a card from a box that was originally filled with 10 control and 10 experimental cards"
Allocation concealment (selection bias)	High risk	"Subjects drew a card from a box that was originally filled with 10 control and 10 ex- perimental cards" Judged at high risk, as concealment would have been broken once 10 were in one group
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	The assessor was blinded for some assess- ments. The outcome measures for which there was no blinded assessor were recorded by computer However, the assessor could have encour- aged some participants more than others
Incomplete outcome data (attrition bias) All outcomes	Low risk	19/20 completed intervention and final as- sessment Dropouts accounted for: "One subject from the control group dropped out of the study because of an acute neurological episode that required hospitalization"
Free of systematic differences in baseline characteristics of groups compared?	Low risk	"no significant differences between the groups in terms of age, time since stroke, or walking velocity"

Did authors adjust for baseline differences in their analyses?	Low risk	No information provided
Other bias	High risk	One therapist (principal investigator) car- ried out all treatments. The use of only one therapist provides a potential source of con- tamination between groups or the intro- duction of performance bias
Dean 2000		
Methods	Study design: RCT Method of randomisation: After baseline measurement, participants were grouped into matched pairs according to their average gait speed. Participants in each pair were ran- domly assigned to experimental or control group, using an independent person to draw cards from boxes	
Participants	Number of participants: n = 12 Inclusion criteria: first stroke, more than three months post stroke, discharged from rehabilitation, able to attend rehabilitation centre three times a week for four weeks and able to walk 10 m independently Exclusion criteria: any medical condition that would prevent participation in a training programme	
Interventions		

	 Length of intervention period: four weeks Number of sessions and length of individual sessions: one-hour programme, three days/wk Intervention provider: "All training sessions were organized into a group exercise class, conducted by the one of the investigators who was assisted by another physiotherapist" (2) Placebo group (n = 6) Standardised circuit programme designed to improve function of the upper limb The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising attention control (upper limb) Length of intervention period: four weeks Number of sessions and length of individual sessions: one-hour programme, three days/wk Intervention provider: "All training sessions were organized into a group exercise class, conducted by the one of the investigators who was assisted by another physiotherapist" This study was classified as intervention (functional task training, musculoskeletal (active)) versus attention control (upper limb) (Table 5)
Outcomes	Measures of voluntary movement: timed 10-Metre Walk; Six-Minute Walk test; Step test; Timed Up and Go test; laboratory gait assessment
	Other measures: strength and dexterity of the upper limb Time points when outcomes were assessed: "Subjects were evaluated three times: before the training (pretraining), at the end of the training (posttraining), and 2 months later (follow-up)"
Notes	

Notes

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	After baseline measurement, participants were grouped into matched pairs according to their average gait speed. Participants in each pair were randomly assigned to exper- imental or control group, using an inde- pendent person to draw cards from boxes
Allocation concealment (selection bias)	Unclear risk	Although participants were paired accord- ing to average gait speed, it is not clear how this matching was performed; if the per- son doing the matching was not blind to the other characteristics of the participants, there is the potential for selection bias
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	The assessor was blinded for all assessments except one (Six-Minute Walk test)

Incomplete outcome data (attrition bias) All outcomes	Low risk	Dropouts accounted for Nine of 12 completed training and pre- training and post-training assessments Eight of 12 completed follow-up (two- month) assessment
Free of systematic differences in baseline characteristics of groups compared?	Low risk	"Subjects completed the pretraining evalu- ation and were then grouped into matched pairs according to the average walking speed at the pretraining evaluation"
Did authors adjust for baseline differences in their analyses?	Low risk	No information provided
Other bias	High risk	The same therapist conducted the training sessions for both groups and was respon- sible for progression of treatment, etc; this may potentially contaminate the groups The study included only participants who were able to travel to the rehabilitation cen- tre and prepared to meet the costs of this. The results of this study therefore can be applied only to equally motivated partici- pants
Dean 2006		
Methods	Study design: prospective, multi-centre, parallel RCT Method of randomisation: "eligible participants were randomly allocated within each stroke club to an experimental group (EG) or a control group (CG), using random permuted blocks of 2 to 6 participants. The allocation sequence was computer generated before commencement of the study, and a set of consecutively numbered, sealed opaque envelopes containing the allocation was centrally generated for each stroke club"	

Participants	Number of participants: n = 151 Inclusion criteria: "participants were invited to participate if they had suffered 1 or more strokes, were able to walk 10 m independently with or without a mobility aid, gained medical clearance, were willing to join the NSW Stroke Recovery Association and commit to a weekly exercise class and home program for 12 months, and were able to give informed consent" Exclusion criteria: "Folstein Mini-Mental State Examination score of less than 20, insuf- ficient language skills to participate in assessment and intervention, and a medical con- dition precluding exercise, such as unstable cardiovascular disease or other uncontrolled chronic conditions that would interfere with training and testing protocols"	
Interventions	(1) Experimental group (EG) (n = 76) The EG received an exercise intervention designed to enhance mobility, prevent falls and increase physical activity-the WEBB programme. The programme involved "task-	

Outcomes Measures of postural control and balance: Timed Up and Go test, Step test, Timed 5 STS, maximum balance range Measures of voluntary movements: Six-Minute Walk test, 10-Metre Walk test Measures of muscle strength: knee strength (affected and intact) Measures of participation: Adelaide Activities Profile Measures of quality of life and social isolation: Health-Related Quality of Life SF (Short Form)-12, version two Other secondary outcome measures: falls risk (Short-Form Physiological Profile Assessment), seven-day pedometer count, choice stepping reaction time, co-ordinated stability Time points when outcomes were assessed: at baseline and at month 12 "Interventions were tailored to the participant's functional ability. The nature and difficulty of the exercises were progressed regularly to ensure that the intervention remained challenging"		related" training with progressive balance and strengthening exercises, as well as walking and stair climbing. Typical exercises included calf raisers while standing, sit-stand, step- ups, standing with reduced base of support, graded reaching activities in standing and forward, backward and sideways stepping and walking. The intervention was delivered in a weekly circuit-style group exercise class and a home exercise programme, and advice to increase walking was given The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising functional task training and musculoskeletal intervention (active) Length of intervention period: "Classes planned to be delivered weekly for 40 weeks over a 1-year period and a home exercise program to be completed at least 3 times per week" Number of sessions and length of individual sessions: "Each class and home program session was designed to take 45 to 60 minutes" Intervention provider: "exercise classes were delivered by a physiotherapist who also designed individual home programs, which were reviewed and modified monthly" (2) Control group (CG) (n = 75) "The CG exercise class was designed to improve upper-limb function, manage upper- limb contracture with task-related strength and coordination training, and improve cog- nition with matching, sorting and sequencing tasks. The CG was also prescribed a home program aimed to make them use their affected arm and keep their mind occupied with cognitive leisure tasks such as word and number puzzles" The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising upper limb training Length of intervention period: "Classes planned to be delivered weekly for 40 weeks over a 1-year period and a home exercise program to be completed at least 3 times per week" Number of sessions and length of individual sessions: "Each class and home program session was designed to take 45 to 60 minute
culty of the exercises were progressed regularly to ensure that the intervention remained	Outcomes	STS, maximum balance range Measures of voluntary movements: Six-Minute Walk test, 10-Metre Walk test Measures of muscle strength: knee strength (affected and intact) Measures of participation: Adelaide Activities Profile Measures of quality of life and social isolation: Health-Related Quality of Life SF (Short Form)-12, version two Other secondary outcome measures: falls risk (Short-Form Physiological Profile Assess- ment), seven-day pedometer count, choice stepping reaction time, co-ordinated stability
	Notes	culty of the exercises were progressed regularly to ensure that the intervention remained

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	"Random permuted blocks of 2 to 6 partic- ipants. The allocation sequence was com- puter generated before commencement of the study, and a set of consecutively num- bered, sealed opaque envelopes containing the allocation was centrally generated for each stroke club"
Allocation concealment (selection bias)	Low risk	"The experimental and control classes were held in different areas of the stroke club and at different times to minimize the risk of 'contamination' between the groups"
Blinding of outcome assessment (detection bias) All outcomes	Low risk	"The participants and therapists delivering the intervention could not be blinded to intervention group allocation. Falls were recorded from self-report calendars. All other outcome measures were collected by an assessor who was blinded to group al- location. Blinding was ensured using sev- eral strategies. Participants were asked not to reveal details of their program to the as- sessors, and assessments were collected out- side the times for exercise classes"
Incomplete outcome data (attrition bias) All outcomes	Low risk	Dropouts accounted for At month 12, 11 participants were lost to follow-up in the experimental group: in- continence (n = 1), moved (n = 2), carer illness (n = 2) and illness (n = 6). At month 12, seven participants were lost to follow- up in the control group: died (n = 3), illness (n = 2) and refused classes/reassessment (n = 2) "of 18 withdrawals, only 1 was related to the intervention: 1 participant withdrew as the experimental exercise exacerbated an incontinence problem"
Free of systematic differences in baseline characteristics of groups compared?	Low risk	"At baseline, the groups were similar in terms of demographic characteristics and other comorbidities"
Did authors adjust for baseline differences in their analyses?	Low risk	No information provided

Methods	by using sealed opaque envel by a person independent of	Study design: RCT Method of randomisation: "Randomisation was concealed from the recruiter and assessor by using sealed opaque envelopes containing the allocation, which was generated earlier by a person independent of the study using random number tables, blocked to ensure equal numbers of experimental and control participants"	
Participants	Inclusion criteria: diagnosis three months, no orthopaed seated reaching tasks, no visi objects or reading, score of Assessment Scale for Stroke (lent to 140% of arm's length, the short portable mental sta using the Letter Cancellatio	Number of participants: n = 12 Inclusion criteria: diagnosis of first stroke resulting in hemiplegia within the previous three months, no orthopaedic problems that would interfere with the ability to perform seated reaching tasks, no visual problems that would interfere with reaching to pick up objects or reading, score of at least three on item three (sitting balance) of the Motor Assessment Scale for Stroke (Carr 1985), able to reach with intact arm a distance equiva- lent to 140% of arm's length, no major cognitive or perceptual problems identified using the short portable mental status questionnaire (Pfeiffer 1975), no left neglect identified using the Letter Cancellation Test (Wilson 1987), able to give informed consent and able to understand instructions	
Interventions	"During the training period p intervention other than train other multidisciplinary reha "Participants in the experime by Dean 1997. Designed to unaffected hand whilst focu arm to get the hand to the (3) preventing the use of m While reaching beyond arm's and task were varied systems increasing the reach distance The individual components components, this intervention Length of intervention period Number of sessions and ler lasting approximately 30 mi Intervention provider: physi dents (2) Control group group (n "Participants in the control g improve attention (Dean 199 consider themselves involved due to placebo. This training manipulative tasks. Participants	(1) Experimental group (n = 6) "During the training period participants in both groups received all regular physiotherapy intervention other than training to improve sitting. All participants continued to attend other multidisciplinary rehabilitation services" "Participants in the experimental group were given the sitting training protocol designed by Dean 1997. Designed to improve sitting by reaching beyond arm's length using the unaffected hand whilst focusing on: (1) smooth coordinated motion of the trunk and arm to get the hand to the object; (2) appropriate loading of the affected foot; and (3) preventing the use of maladaptive strategies such as widening the base of support. While reaching beyond arm's length, reach distance, direction, thigh support, seat height, and task were varied systematically. Training was progressed over the 2-week period by increasing the reach distance and the number of repetitions" The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising functional task training Length of intervention period: two weeks Number of sessions and length of individual sessions: 10 sessions, with each session lasting approximately 30 minutes Intervention provider: physiotherapist or supervised undergraduate physiotherapy stu- dents (2) Control group group (n = 6) "Participants in the control group completed a sham sitting training protocol designed to improve attention (Dean 1997). Sham training was performed so that participants would consider themselves involved in a training program, which would eliminate any effect due to placebo. This training involved participants completing a series of 11 cognitive- manipulative tasks. Participants were seated at a table, well supported in a chair with back and armrests, with their forearms resting on the table. The workspace was confined	

	to balance. Training was progressed over the 2-week period by increasing the number of repetitions and cognitive difficulty of the cognitive-manipulative tasks. Therefore, this training was sham sitting training because the perturbations to balance were minimal and were unlikely to lead to improvements in sitting" The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising attention control (cognitive training) Length of intervention period: two weeks Number of sessions and length of individual sessions: 10 sessions, with each session lasting approximately 30 minutes Intervention provider: physiotherapist or supervised undergraduate physiotherapy student This study was classified as intervention (functional task training) versus attention control (cognition) (Table 5)
Outcomes	Measures of postural control and balance: sitting ability (maximum reach distance), sitting quality Measures of voluntary movements: 10-Metre Walk test (comfortable speed) Other secondary outcome measures: carryover to mobility (standing up and walking) Time points when outcomes were assessed: "prospective randomised design with pre-, post-, and follow-up tests (six months later)"

Methods	Study design: RCT Method of randomisation: based on the "unbalance index minimum principle," age, nature of lesion, side of lesion, commencement of treatment time and cognitive deficits	
Participants	Number of participants: n = 100 Inclusion criteria: first ever stroke, confirmed by CT scan or MRI, satisfied 1995 evalua-	

Inclusion criteria: first ever stroke, confirmed by CT scan or MRI, satisfied 1995 evaluative standard revised by the Fourth [National] Academic Conference of Cerebral Vascular Disease, Glasgow Coma Score > eight, persistent motor deficits, participant or family consent, willing to sign on informed consent sheet Exclusion criteria: severe active liver disease, insufficient function of the liver and/or

kidney, cardiovascular issues, malignant tumour(s), cardiorespiratory issues, inability to comply with investigators, haemorrhage in the eyes and home inaccessible to visiting personnel

Interventions	 (1) Intervention group (n = 50) "Both groups received conventional therapy and nursing care in the Department of Neurology" "The intervention group were also given ADL system intervention. The team looking after the intervention group comprised therapists and rehabilitation nurses. The therapists used Brunnstrom stages of motor recovery to deliver the intervention training, the rehabilitation nurses provided guidance on patient self-care, based on the assessment of patient self-care needs and self-care ability, through 3 care systems, using the methods of full substitution, guidance, encouragement and provision of environment and education to improve the patients' ADL ability" "ADL system intervention content: (a) Acute phase (flaccid paralysis phase): The aim of training is to prevent disuse, prevent possible complications so as to create the conditions for initial training. Initial bedside activities for ADL training include: maintaining positions which prevent spasms; changing body positions; passive ranging exercises through normal joint ranges of motion; passive massages; active bed training: mainly focused on training of truncal muscles, including bridging exercises, rolling to both sides, sitting up from non-affected and affected sides etc: (b) Early recovery phase (spastic phase): The aim of training is to reduce muscle tension, resolve spasticity and exercise in isolated movements, detailed content includes: sitting balance training at levels 1, 2, 3; supported and assisted stepping exercises (c) Middle and late recovery phase (equivalent to recovery phase): When spasms are more or less under control, the aim of training is to generate fine, coordinate, quick random movements. Detailed content includes: continuation of gait reeducation and postural correction, so as to allow further improvement of body function; upper limb and hand isolated movement training." The individual components delivered are liste
	to provide training during participants' follow-up visits, frequency unchanged; rehabil- itation nurses provided home ADL system Intervention provider: therapists and rehabilitation nurses

Methods

Study design: RCT

Method of randomisation: "Randomization was done in blocks of 10. Before initiation of this study, a random list was generated by group assignments"

Participants	Number of participants: n = 20 Inclusion criteria: 30 to 90 days post stroke, Fugl-Meyer score of 40 to 90, Orpington prognostic score two to 52, ambulatory with supervision or assistive device, or both, living at home (less than 50 miles from Kansas), no medical condition that would limit participation, Mini Mental State score greater than 18 and able to follow three-step command
Interventions	 (1) Mixed group (n = 10) Home-based programme aiming to improve "strength, balance and endurance and to encourage more use of the affected extremity" Assistive and resistive exercises; proprioceptive neuromuscular facilitation (PNF); Theraband exercises; balance exercises; functional activities for the affected upper extremity; progressive walking programme; progressive bicycle ergometer exercise "The study investigator and co-investigator observed at least 1 therapy session for each subject to ensure standard application of interventions" Treatments followed a detailed written protocol for intervention The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising cardiopulmonary interventions, functional task training, musculoskeletal interventions (active) and neurophysiological interventions Length of intervention period: eight weeks and instructed to continue programme on own for further four weeks Number of sessions and length of individual sessions: approximately 1.5 hours, three/wk Intervention provider: physical therapist and occupational therapist (2) Control group (n = 10) Usual care: "the therapy programmes received by the control group varied in intensity, frequency and duration" Types of exercise interventions given were balance training (60%), progressive resistive exercises (40%), bimanual activities (50%) and facilitative exercises (30%) The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising usual care (functional task training, musculoskeletal (active) and neurophysiological intervention) Length of intervention period: "Participants in this group were visited by a research assistant every 2 weeks to assess the patients' exercise and activity level. Duration of surveillance was 12 weeks" Number of s
Outcomes	Measures of independence in ADL: Barthel Index; Lawton Instrumental ADL Measures of functional independence: Fugl-Meyer Motor score Measures of postural control and balance: Berg Balance Scale

Based on the individual components, this intervention is categorised as comprising cardiopulmonary interventions, functional task training, musculoskeletal interventions (active) and neurophysiological interventions Length of intervention period: 12 to 14 weeks Number of sessions and length of individual sessions: 36 sessions of 90 minutes Intervention provider: supervised by physiotherapist or occupational therapist 	

Duncan 2003 (Continued)

	durance, upper extremity, range of motion, mobility and ADL/IADL The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising usual care (functional task training, musculoskeletal intervention (active)) Length of intervention period: varied Number of sessions and length of individual sessions: visited by researcher every two weeks Intervention provider: physiotherapists and occupational therapists This study was classified as intervention (functional task training, musculoskeletal in- terventions (active) and neurophysiological interventions) versus usual care (functional task training, musculoskeletal (active)) (Table 5). The intervention group also received cardiopulmonary intervention
Outcomes	Measures of functional independence: Fugl-Meyer (LL) Measures of postural control and balance: Berg Balance Scale score Measures of voluntary movement: gait velocity Measures of muscle strength: ankle and knee strength Time points when outcomes were assessed: "primary outcomes of the study were assessed at 3 months, immediately after the intervention"

Notes

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Blocked randomisation (block size six), random number generator and sealed en- velopes "After baseline assessments, the subjects were randomly assigned to the intervention or control group through the use of a ran- dom number generator with a block size of 6 and sealed envelopes"
Allocation concealment (selection bias)	Low risk	No information provided
Blinding of outcome assessment (detection bias) All outcomes	Low risk	The assessor was blinded "Outcome assessment was performed by research staff blinded to treatment assign- ment. Participants were instructed to avoid mentioning anything regarding their study experience to the assessors. Participants were not blinded to their assignment but were unaware of the study hypotheses or primary outcome measures"

Duncan 2003 (Continued)

Incomplete outcome data (attrition bias) All outcomes	Low risk	Dropouts accounted for 92/100 completed intervention and three- month follow-up
Free of systematic differences in baseline characteristics of groups compared?	Low risk	No significant differences in baseline char- acteristics of intervention, control and dropout groups except on the Wolf Mo- tor Function test ("significantly different in those who did vs did not drop out")
Did authors adjust for baseline differences in their analyses?	Low risk	No information provided
Other bias	High risk	Participants in the intervention group re- ceived greater contact with therapists than participants in the control group, pro- viding a potential source of performance bias. However, 54% of the control group did receive rehabilitation from physiother- apists and occupational therapists during the study period. This 'usual care' may have made the control and treatment groups similar in the rehabilitation they received, potentially reducing the effect of the inter- vention

Fan 2006

Methods	Study design: RCT Method of randomisation: "Stratified by the type of stroke, ischaemic or haemorrhagic, into the two groups"
Participants	Number of participants: n = 82 (of whom two in the control group died) Inclusion criteria: using the 1995 evaluative standard revised by the Fourth [National] Academic Conference of Cerebral Vascular Disease, assessed whether stroke type was ischaemic or haemorrhagic and confirmed by CT scan or MRI, willing to provide in- formed consent, medically stable within one week, Glasgow Coma Scale score greater than eight, aged between 40 and 80 years and had motor deficits Exclusion criteria: active liver disease, compromised liver or kidney function, cardiovas- cular disorder, malignant tumour(s), history of intellectual disorders, cardiorespiratory issue(s), paralysis of four limbs, ischaemic or haemorrhagic stroke outwith three weeks, inaccessible homes located in the outskirts, psychological illness(es) and 'deaf, mute' in- dividuals
Interventions	(1) Treated group (n = 42)"Therapists delivering the rehabilitative treatment all underwent the same training. For acute stroke patients, up to one month after stroke, the first phase of treatment was undertaken, mainly carried out in the Department of Neurology ward, and while given

conventional medical treatment, these patients were given early bedside rehabilitative treatment after becoming medically stable, focusing on physiotherapy, with rehabilitative treatment commencing within 1 week after patients were medically stable; for sub-acute stroke patients, the second (beyond 1 to 3 months after stroke) and third phase (beyond 3 to 6 months after stroke) of treatment [were] undertaken, and based on the patient's condition and level of functional recovery, patients were transferred to rehabilitation ward/centre for further rehabilitation, or discharged home, where a therapist would conduct home visits to guide the patient, and help the patient conduct necessary functional training, until the end of follow-up. Here, 'stage one rehabilitation' referred to the patient's carly conventional medicine treatment at the hospital's emergency or Department of Neurology ward, as well as early stage rehabilitative treatment, 'stage two rehabilitation' referred to the patient's rehabilitation of rehabilitative treatment at the rehabilitation ward/centre, 'stage three rehabilitation' referred to the continuation of rehabilitative treatment at the community or home setting

The rehabilitative treatment method combined physiotherapy and occupational therapy into a holistic method: early stage of treatment was focused on physiotherapy, progressing to occupational therapy. Physiotherapy treatment included: (1) supine and sitting positions to combat spasticity; (2) passive ranging exercise of all affected limb joints, including mobilisation of the shoulder girdle, starting from small to large ranges of motion, to avoid causing pain to the patient; (3) rolling practice (from affected and nonaffected sides); (4) bridging exercises; (5) exercises in ankle dorsiflexion and wrist extension; (6) outwith therapy time, sitting practice: headrest of bed lifted to 30 degrees, and, if participant could tolerate the angle for longer than 30 minutes, the angle was increased by another 10 degrees the following day, until participant could tolerate 90 degrees for longer than 30 minutes, which would then be followed by lying-to-sitting up training (from non-affected and affected sides); (7) sitting balance training (sitting on edge of bed) ; (8) sit-to-stand training; (9) standing balance training; (10) gait training, etc. During the flaccid phase, focus was on postural correction, passive activities and active/passive practice, rolling, lying-to-sitting on edge of bed. During the spasticity phase, focus was on relaxation practice for spastic muscles, antispasticity manual techniques and muscle training for non-spastic muscles, as well as practising exercises in isolated movements. Occupational therapy treatment was based largely on the participant's functional ability at each stage; the appropriate intervention would be given, namely, feeding, grooming, donning, bed-to-wheelchair and wheelchair-to-bed transfer and other ADLs, as well as practice of woodwork, sewing and other handicrafts and ring-insertion games, jigsaws and other leisure activities

Stage one rehabilitation included antispasticity positioning, passive training of limbs, active training of non-affected limbs under guidance and deep breathing, as well as training of abdominal muscles, sitting up from lying, sitting balance and standing up training, etc, to train the participant's ability to get up from the bed (treatment was done), one/ d, 45 minutes/session, five/wk, during the training period, the participant's family or nursing workers were taught the correct supplementary exercises and methods of care concurrently, to achieve partial training out with therapy times, while reducing the damage to affected limbs due to inappropriate nursing care; stage two rehabilitation mainly consisted of standing training, standing balance, single-leg standing, gait training and up-and-down stair training etc, to train the participant's ability to ambulate (treatment was done) 2x/day, 30-45 minutes/session, 5x/week; stage three rehabilitation mainly consisted of feeding, donning, grooming, personal hygiene management and other ADL

Outcomes	centre were delivered by therapists, while c nursing workers how to assist the participanity rehabilitation, therapists conducted for occupational therapy and necessary physiod nursing workers how to help the participan in completing the remaining daily necessary. The individual components delivered are components, this intervention is categoris musculoskeletal intervention (active) and m Length of intervention period: not stated Number of sessions and length of individual Stage one rehabilitation: one/d, 45 minutes Stage two rehabilitation: two/d, 30 to 45 m Stage three same usual medical treatmen patients self-trained after verbal advice from assisted the patient in movement based on t some patients underwent certain rehabilitation rehabilitation organisations upon discharge The individual components delivered are components, this intervention is categorised Length of intervention	Number of sessions and length of individual sessions: dependent on stage of rehabilitation Stage one rehabilitation: one/d, 45 minutes/session, five/wk Stage two rehabilitation: two/d, 30 to 45 minutes/session, five/wk Stage three rehabilitation: two/d, 30 to 45 minutes/session, five to seven days/wk Intervention provider: therapists (participant's family or nursing worker outwith therapy times) (2) Control group (n = 40) (of whom two died) "Patients in the control group were not given any standardised rehabilitation therapy, but were given the same usual medical treatment as the treated group. It was noted that some patients self-trained after verbal advice from their doctor, while some patients' families assisted the patient in movement based on their own knowledge, and the possibility that some patients underwent certain rehabilitation treatment after seeking help from other rehabilitation organisations upon discharge could not be excluded" The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising no intervention Length of intervention period: not stated Number of sessions and length of individual sessions: not stated	
Notes	Original study translated from Chinese to English No data suitable for analysis

Fang 2003			
Methods	Study design: RCT Method of randomisation: "Randomization was achieved through computer-generated random numbers in sealed envelopes"		
Participants	Number of participants: n = 156 Inclusion criteria: "All patients with stroke admitted from 1 August 1998 to 1 November 2001 were considered for inclusion in the study, stroke was defined as acute onset of neurological deficit lasting more than 24 hours or leading to death, with no apparent cause other than cerebrovascular disease. The diagnosis of stroke was based on history and clinical examination. All stroke patients had a CT scan or MRI scan within the first week of stroke onset to confirm the diagnosis" Exclusion criteria: "Patients with signs and symptoms of subarachnoid haemorrhage, transient ischaemic attack, and those with severe cerebral oedema, subjects with Glasgow Coma Scale score of 8 or less or with affected limb muscle power grading 3, premorbid dementia or premorbid severe impairment of the limb, patients who reached the hospital more than one week after stroke onset, abnormal high fever, severe pneumonia and cardiac infarction, severe high blood pressure over 200/120 mmHg, unable to tolerate a 45-minute physiotherapy session daily and patients scheduled to be discharged from the hospital within the first week"		
Interventions	 (1) Additional early physiotherapy (AEP) intervention group (n = 78) "The early therapy included Bobath techniques and passive movements training of the affected limb, and was initiated within the first week after stroke onset. Passive movement training included a series [of] movements of the joints of completely paralytic limbs to prevent contracture and malformation" The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising musculoskeletal intervention (passive) and neurophysiological intervention Length of intervention period: four weeks Number of sessions and length of individual sessions: 45 minutes/d, five days/wk 		

	Intervention provider: " two experienced rehabilitation therapists from the department of rehabilitation in the hospital" (2) Routine therapy (RT) group (n = 78) " routine therapy group received no professional or regular physiotherapy during the whole hospitalization period" The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising no intervention Length of intervention period: no intervention Number of sessions and length of individual sessions: no intervention Intervention provider: no intervention This study is classified as intervention (musculoskeletal (passive), neurophysiological) versus no treatment (Table 4)
Outcomes	Measures of independence in ADL: modified Barthel Index Measures of functional independence: Fugl-Meyer Assessment (upper limb and lower limb) Other measures: Glasgow Coma Scale (GCS), Mini-Mental State Examination (MMSE) , Clinical Neurological Deficit Scale (CNDS) Time points when outcomes were assessed: "follow-up assessments of the above outcome measures were performed 30 days and six months respectively since stroke onset"
Notes	"Stroke related symptoms and complications in each group were treated with multi- disciplinary approaches in the stroke centre by a special team. No special cognitive or acupuncture therapy was administered" This study had high numbers of dropouts from the treatment group (28/78 from treat- ment group during treatment period) as compared with no dropouts from the control group. Large numbers were lost to follow-up from both groups for the six-month follow- up (with only 12/50 and 14/78 included at six months)

Risk of bias

Bias	Authors' judgement	Support for judgement

Outcomes	Measures of participation: ADL; "ADL was assayed for all participants" Time points when outcomes were assessed: "primary assay should be done within 7 days after onset, while the final assay [should] be carried out 3 months after onset"
Notes	Abstract only-limited information available Mismatch in number of participants reported (total of 40, but when broken down into the two groups, 20 in the rehabilitation group and 28 in the control group). Need to contact study authors to clarify this point Middle-frequency therapy is well described in the methods No data suitable for analysis

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	No information provided "40 patients with acute stroke admitted during 2002-01/06 were randomly divided into two groups"
Allocation concealment (selection bias)	Unclear risk	No information provided
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	No information provided
Incomplete outcome data (attrition bias) All outcomes	Unclear risk	No dropouts, but a mismatch in participant numbers needs clarification
Free of systematic differences in baseline characteristics of groups compared?	Low risk	"No significant difference" in the baseline ADL score between groups, and age-gender similar across groups
Did authors adjust for baseline differences in their analyses?	Low risk	No information provided

Other bias	Unclear risk	Very little information available about length of intervention provided to the treat- ment group	
Gelber 1995			
Methods	Study design: RCT Method of randomisation: "pa	atients were randomised to one of two treatment arms"	
Participants	Inclusion criteria: pure motor stroke; no cognitive, language	Number of participants: n = 27 Inclusion criteria: pure motor hemiparetic ischaemic stroke, less than one month post stroke; no cognitive, language, visual, sensory or bilateral deficits; no history of stroke and no premorbid use of walking stick	
Interventions	movements with progression functional activities. Therapy activities, and encouraged pat use of abnormal reflexes and m training and evaluation in use treatment The individual components of components, this intervention neurophysiological intervention Length of intervention periods tient rehabilitation programme Number of sessions and length Intervention provider: "these apists and occupational therap the patients' time as both inp tered according to allocated tr of techniques that patients wei (2) Orthopaedic group (traditi "Practicing functional tasks a abnormal postures" "Passive range of movement; to of unaffected side to perform evaluation in the use of the app The individual components of components, this intervention task training, musculoskeletal (passive) Length of intervention periods tient rehabilitation programme	scle tone and initiation of normal (good quality) motor through developmental sequences prior to advancing to techniques included tone inhibition and weight bearing tients to use their affected side. Resistance exercises and hass movements were avoided." All therapists had received e of the approaches and were given 'strict guidelines' for delivered are listed in Table 3. Based on the individual is categorised as comprising functional task training and on : "continued for the duration of the inpatient and outpa- es" h of individual sessions: not stated treatment approaches were used by both the physiother- pists who treated the patients, and were used throughout batients and outpatients. All interventions were adminis- reatment group. The nursing staff reinforced any practice ional functional retraining: TFR) (n = 12) as early as possible even in the presence of spasticity or resistive exercises; assistive devices and bracing allow use functional tasks. Therapists had all received training and proaches, and were given 'strict guidelines' for treatment" delivered are listed in Table 3. Based on the individual n is categorised as comprising assistive devices, functional interventions (active) and musculoskeletal interventions the 'continued for the duration of the inpatient and outpa- es''' h of individual sessions: not stated	

Gelber 1995 (Continued)

	This study is classified as active intervention one (functional task training, neurophys- iological) versus active intervention two (functional task training, musculoskeletal (ac- tive), musculoskeletal (passive)) (Table 6). Intervention group two also received assistive devices
Outcomes	Measures of Independence in ADL: Functional Independence Measure Measures of voluntary movement: parameters of gait Other measures: length of stay and inpatient hospital costs; Box and Block test; 9-Hole Peg test Time points when outcomes were assessed: "All of the outcome measures were evaluated at admission, discharge, six months and at twelve months follow-up"

Notes

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	No information provided ("patients were randomised to one of two treatment arms")
Allocation concealment (selection bias)	Unclear risk	No information provided
Blinding of outcome assessment (detection bias) All outcomes	High risk	Unclear whether the participant was blinded Therapist was not blinded The same therapists provided treatment to participants in both treatment groups, cre- ating a possibility of contamination be- tween the groups Assessor was not blinded
Incomplete outcome data (attrition bias) All outcomes	Unclear risk	Dropouts accounted for 27/27 completed intervention 16/27 at follow-up assessments (23/27 for Functional Independence Measure, carried out by telephone)
Free of systematic differences in baseline characteristics of groups compared?	Low risk	"NDT and TFR treated patients did not differ with respect to age, gender, side of stroke or days from stroke to entry in the study"
Did authors adjust for baseline differences in their analyses?	Low risk	No information provided
Other bias	Unclear risk	The nursing staff reinforced any practice of techniques that participants were to carry out outside of their treatment sessions; this

	difference in nursing care may introduce performance bias
Green 2002	
Methods	Study design: RCT Method of randomisation: blocked randomisation (numbered, sealed, opaque envelopes prepared from random number tables. Assignment by independent person)
Participants	Number of participants: n = 170 Inclusion criteria: aged over 50 years, stroke longer than one year previously and persisting mobility problems Exclusion criteria: non-stroke mobility problem, dementia, severe co-morbidity, bed bound and physiotherapy in previous six months
Interventions	 (1) Mixed: community physiotherapy using a problem-solving approach (n = 85) "Physiotherapy treatment was done by an established community physiotherapy service (13 staff) as part of their usual work" Community physiotherapists assessed using a 'problem solving approach' and administered interventions according to the problem identified Physiotherapy interventions included: "gait re-education, exercise therapy, balance re-education, counselling and advice, neurological mobilisations, functional exercises, posture re-education, other interventions" The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising functional task training Length of intervention period: maximum of 13 weeks Number of sessions and length of individual sessions: minimum of three contacts per participant ("median number of treatments per patient was three (IQR 2 to 7, range 0 to 22) and the mean duration of every treatment was 44 min") Intervention provider: physiotherapists (2) Control: no intervention (n = 85) No treatment The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising no intervention Length of intervention period: no intervention Number of sessions and length of individual sessions: no intervention Length of intervention is categorised as comprising no intervention Length of intervention period: no intervention
Outcomes	Measures of Independence in ADL: Barthel Index Measures of functional independence: Rivermead Mobility Index, Frenchay Activities Index Measures of voluntary movement: gait speed Other measures: Hospital Anxiety and Depression Scale; Depression, General Health Questionnaire 28; number of participants who had falls Time points when outcomes were assessed: "After baseline assessment, follow-up assess- ments were 3-monthly until 9 months"

Notes

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Blocked randomisation (numbered, sealed, opaque envelopes prepared from random number tables. Assignment by indepen- dent person)
Allocation concealment (selection bias)	Low risk	Assignment was by independent person
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Unclear whether the participant was blinded Therapist was not blinded Assessor was blinded
Incomplete outcome data (attrition bias) All outcomes	Low risk	Dropouts accounted for 161/170 completed intervention 151/170 at six-month assessment
Free of systematic differences in baseline characteristics of groups compared?	Low risk	"The characteristics of the two groups were reasonably similar at baseline"
Did authors adjust for baseline differences in their analyses?	Low risk	No information provided
Other bias	Unclear risk	No information provided

Holmgren 2006

Methods	Study design: single-centre, single-blinded RCT Method of randomisation: "Randomization of subjects into the intervention (IG) or control group (CG) was conducted with a minimization software program, MiniM (29) to avoid baseline risk factor imbalances between the two groups. Two variables were taken into account: cognition, using the Mini Mental State Examination, MMSE and fall risk, using the Fall Risk Index"
Participants	Number of participants: $n = 34$ Inclusion criteria: first ever or recurrent ischaemic or haemorrhagic stroke three to six months before enrolment and randomisation, age ≥ 55 years, ability to walk 10 metres with or without a walking device, ability to understand and comply with instructions in Swedish and at risk of fall (at the time of enrolment) Exclusion criteria: ability to walk outdoors independently, without personal assistance or walking device, severe aphasia or severe vision or hearing impairment, medical condition that a physician determined was inconsistent with study participation (e.g. cancer or

	severe congestive heart failure with expected short remaining life expectancy, recurrent stroke within three months before study start) and if the individual lived farther than 100 km away from the training facilities ("this was considered as too far away, since it would take too much time and energy away from the individual each day of the intervention")
Interventions	 (1) Intervention group (n = 15) "The focus of the exercise was on physical activity and functional performance (based on the HIFE program), to improve the subjects' lower-limb strength, balance and gait ability. The program includes lower-limb strength (e.g. chair stand) and balance exercises (e.g. weight shifting outside support surface), standing (e.g. knee bend) and walking (e.g. obstacle crossing course)" "The two daily training sessions were divided between exercise according to the HIFE program and implementing of the same in to everyday life activities, e.g. walking outdoors or sweep the yard. All exercises were performed at a high intensity, if possible, for each subject. 'High intensity' was defined as (i) strength exercises comprising at least two sets of exercises with 8 - 12 repetitions (maximum), (ii) the balance exercises were close to the subject's balance maximum, and (iii) the subject did not rest more than necessary, all according to the HIFE program" "In addition, there was a 1-hour educational discussion session, per week. These discussions were about the increased risks of complications after stroke, such as falls. During the last week of intervention, an individualized home-based exercise program was designed by the physiotherapist. This home exercise program was part of the intervention program and consisted of a maximum of three different exercises that were based on the exercises performed during the 5-week intervention. It was easy to adjust the intensity of all the exercises of that they could be modified as the subject progressed. The instructions were to perform this home-based exercise program three times a week at least until the 3-month follow-up" The individual components delivered are listed in Table 3. Based on the individual components; this intervention is categorised as comprising functional task training and muscloskeletal intervention (active) Length of intervention period: five weeks. In addition, participants were in

Holmgren 2006 (Continued)

	Number of sessions and length of individual sessions: "met once a week for 1 hour of educational session" Intervention provider: occupational therapist This study is classified as intervention (functional task training, musculoskeletal (active)) versus no treatment (Table 4)
Outcomes	Measures of independence in ADL: Barthel Index Measures of postural control and balance: Berg Balance Scale Measures of participation: Frenchay Activities Index last three months (FAI-3) tertially Other secondary outcome measures: Falls Efficacy Scale-International (FES-I) and num- ber of falls Time points when outcomes were assessed: "Assessments were done at baseline, post- intervention, 3- and 6-month follow-up"
Notes	SD computed from confidence intervals and P value

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	"Randomization of subjects into the inter- vention (IG) or control group (CG) was conducted with a minimization software program, MiniM (29) to avoid baseline risk factor imbalances between the two groups. Two variables were taken into account: cog- nition, using the Mini Mental State Exam- ination, MMSE and fall risk, using the Fall Risk Index"
Allocation concealment (selection bias)	Low risk	"Randomization procedure was conducted by the two principal investigators; these two were involved neither in the assess- ments nor in the intervention group or con- trol group. Both investigators were blinded to allocation at the time of randomization, which was made possible by using code numbers for each participant"
Blinding of outcome assessment (detection bias) All outcomes	Low risk	"All assessments were done by blinded staff, who were instructed that if they had any reason to believe that they had revealed a subject's group they should make an ad- verse event report. The staff in the inter- vention did not take part in any of the as- sessments"

Holmgren 2006 (Continued)

Incomplete outcome data (attrition bias) All outcomes	Low risk	Dropouts accounted for "All but one subject completed the entire program, although two subjects dropped out during follow-up; the reason for drop- out was worsening overall medical condi- tion in all three cases"
Free of systematic differences in baseline characteristics of groups compared?	Low risk	"There were no significant differences in the baseline characteristics of the two groups except from the TOAST pathogen- esis classification of ischemic stroke"
Did authors adjust for baseline differences in their analyses?	Low risk	No information provided
Other bias	Unclear risk	No information provided

Hou 2006

Methods	Study design: RCT Method of randomisation: not stated
Participants	Number of participants: n = 80 Inclusion criteria: "Using the 1995 evaluative standard revised by the Fourth [National] Academic Conference of Cerebral Vascular Disease, and confirmation of a first ever stroke from CT or MRI scan, 80 participants were selected" (not explicitly stated as inclusion or exclusion criteria but the text also mentioned "that participants were medically stable within two week of stroke onset; had GCS score of > 8; had deficits in motor function; aged between 40-80 years old") Exclusion criteria: "Active liver/kidney disease, paralysis of four limbs, deaf and/or mute and issues with coordinating assessment or inaccessible homes"
Interventions	 (1) Rehabilitation group (n = 40) "Both groups of patients received conventional clinical treatment and care. Rehabilitation group, besides conventional clinical treatment, also strictly followed 'fifteen' research topics 'cerebrovascular disease three level rehabilitation programme' in carrying out rehabilitation; control group did not perform any standard rehabilitation Rehabilitation group patients, on entering the group, immediately commenced level one rehabilitation programme (within neurology ward), comprising anti-spasticity positioning on bed; breathing exercises; passive ranging exercises on limbs of affected side; use of neural stimulation technique (mainly Rood technique and Brunnstrom technique); active ranging exercises of limbs of non-affected side; lying to sitting training; sitting-balance training; ADL training on bed; neural network and functional electrical stimulation etc. Based on individual situation, selectively performed, 1 - 2/day, 30 - 40 min/ session, 5 days/week" "Over time, patient's condition gradually improved, and they were transferred from neurology ward to rehabilitation zone or rehabilitation centre to continue rehabilitation, i.e. level two rehabilitation, with content based on patient's condition to further intensify

Random sequence generation (selection	TT 1 · 1	No information provided

Allocation concealment (selection bias)	Unclear risk	No information provided
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Outcome assessors did not deliver interven- tion
Incomplete outcome data (attrition bias) All outcomes	Low risk	No dropouts
Free of systematic differences in baseline characteristics of groups compared?	Low risk	No significant difference (P value > 0.05) for gender, age, days after stroke, type of stroke and Brunnstrom score for upper limb, hand and lower limb at baseline
Did authors adjust for baseline differences in their analyses?	Low risk	No information provided
Other bias	Unclear risk	No information provided
Howe 2005		
Methods	Study design: RCT Method of randomisation: "Group allocation was via randomized permutated blocks," by telephone	
Participants	Number of participants: n = 35 Inclusion criteria: aged over 18 years, acute vascular stroke and previously independently mobile indoors and in personal ADL Exclusion criteria: other neurological pathology, drugs or conditions affecting balance, impaired consciousness, dementia, unable to tolerate therapy, 'pusher' syndrome and severe perceptual problems	
Interventions	 (1) Additional therapy (n = 17) Exercises aimed at improving lateral weight transference in sitting and standing. Incorporated elements of motor learning, including repetition (practice) of self initiated goal-oriented activities with, where appropriate, manual guidance and verbal encouragement (feedback). Specific techniques are detailed with an appendix to the published paper. Participants in this group received the same usual care as participants in the usual care group The individual components delivered are listed in Table 3, Based on the individual components, this intervention is categorised as comprising functional task training Length of intervention period: four weeks Number of sessions and length of individual sessions: "as their usual care, 217 sessions, total duration 7135 min." Participants received 12 additional therapy sessions-total of six additional hours over the intervention period ("between them received 181 additional treatment sessions, mean 10.6 sessions, each of 30 min duration, total 5430 min") Intervention provider: delivered by trained physiotherapy assistants (2) Usual care (n = 18) 	

Howe 2005 (Continued)

	"Physiotherapists reported that usual care was loosely based on 'neurophysiological' principles, however, their choice of specific physical interventions during each session was determined on an individual basis based on the symptomatic presentation of the patient at the time" The individual components delivered are listed in Table 3. Based on the individual com- ponents, this intervention is categorised as comprising usual care (neurophysiological) Length of intervention period: four weeks Number of sessions and length of individual sessions: "Patients in the usual care group (n = 18) received 255 sessions of therapy, total duration 8643 min" Intervention provider: physiotherapists This study is classified as intervention (functional task training) versus usual care (neu- rophysiological) (Table 5)
Outcomes	Measures of postural control and balance: lateral reach test, weight distribution in stand- ing, sit-to-stand Time points when outcomes were assessed: "at baseline, four weeks (retest) and eight weeks (follow-up)"
Notes	No outcomes included in analysis; all outcomes were specific to goal of lateral weight transference

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	"were randomly allocated to a usual care only group, or to the treatment group" "Group allocation was via randomized per- mutated blocks. The project manager held details of assignment and revealed these to the recruiting physiotherapist via telephone only when the patient was due to be allo- cated to a group. The code was not broken until all patients had completed the study and all analysis was complete"
Allocation concealment (selection bias)	Low risk	"The project manager held details of assign- ment and revealed these to the recruiting physiotherapist via telephone only when the patient was due to be allocated to a group"
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Participant was not blinded Therapist was not blinded Assessor was blinded (outcome measures "were undertaken by a blind independent observer")

Howe 2005 (Continued)

Incomplete outcome data (attrition bias) All outcomes	Low risk	Dropouts accounted for 33/35 completed intervention 31/35 had eight-week follow-up
Free of systematic differences in baseline characteristics of groups compared?	Low risk	"The groups did not differ (statistically sig- nificantly) in any of these characteristics"
Did authors adjust for baseline differences in their analyses?	Low risk	No information provided
Other bias	Unclear risk	The standard physiotherapy and other usual care procedures could have changed as a direct or indirect result of the addi- tional study intervention Participants could have passed on informa- tion about their additional treatment both to the therapists providing standard care and to other participants in the study
Hu 2007 haem		
Methods	Study design: RCT Method of randomisation: "Randomisation group or haemorrhage group"	done after classifying into cerebral infarction
Participants	Number of participants: n = 352 Inclusion criteria: not stated	
Interventions	 (1) Test group (n = 178 haemorrhagic) "Patients from both groups received the same routine neurological intervention, but the treated group received additional standardised tertiary rehabilitation (STR), with details of training content outlined in references (Research Group 2007)" Length of intervention period: six months Number of sessions and length of individual sessions: not stated Intervention provider: not stated The individual components delivered are listed in Table 4. Based on the individual components, this intervention is categorised as comprising components not stated (2) Control group (n = 174) Received routine neurological intervention Length of intervention period: not stated Number of sessions and length of individual sessions: not stated Intervention provider: not stated The individual components delivered are listed in Table 3. Huang 2003

Methods	Study design: RCT Method of randomisation: stratified randomisation
Participants	Number of participants: n = 50 Inclusion criteria: "Diagnosis of stroke, confirmed by CT or MRI scan, medically stable within a week, did not exceed 2 weeks on enrolment to study, aged 40-80 years, Glasgow Coma Score > 8 and deficits in limb function" Exclusion criteria: "Absence of malignant tumour(s), high blood pressure, no psycholog- ical conditions, not deaf, not mute and not have paralysis of four limbs"
Interventions	(1) Rehabilitation group (n = 25) "Both groups received routine treatment (such as medicine). For the participants in the treatment group, exercise therapy combined Bobath, Rood, Motor Relearning Program and proprioceptive neuromuscular facilitation (PNF) techniques; in terms of electrotherapy, early use of electrical stimulation, acquuncture is carried out, with additional appropriate electrical stimulation for participants with shoulder-hand syndrome. Recovery of each motor function was targeted by using sequential and progressive therapy, using the following methods: (i) correct positioning: teaching patient's family and cargivers the correct limb positioning of limbs in supine position, lateral position with affected limbs at upper side and healthy limbs at uoper side, and lateral position with affected limbs at upper side and healthy limbs at uoper side, requesting changing of body position every two hours. (ii) Rolling practice: with both hands intertwined and both elbows extended in front of the body, participants practised rolling to the left and right, with knees in flexion. (iii) Self-assisted bed exercises: with both hands intertwined, participants extended both elbows in front of the body, overhead, to the left and right, touched the nose and did bridging exercises etc. (iv) Passive ranging bed exercises tupper limb: hip, knee, talo-crural, metatarsal joints. (v) Techniques to facilitate muscle contractions. (vi) Lung clearance: percussions to the posterior segments of the lungs. (viii) Upright sitting training: gradually increasing the inclining angle of the bed, participants at urpight for 30 minutes. Once this was accomplished, the inclining angle is increased by 10 degrees until the participant could sit on the edge of bed. (viii) Stimulation to the muscles of the face, tongue and lips: opening of mouth, budging of cheeks, gritting of teeth, extending the tongue, placing the tongue on the upper plate, iced cotton swabs (or placing ice cubes in the buccal cavity) and stimulation of taste. (ix)

Huang 2003 (Continued)

	standing training within 2 weeks, with the level of assistance given depending on the medical status of the participants; participants with haemorrhagic stroke should aim to sit on the edge of bed within 2 weeks of rehabilitation and commencement of standing training within 4 weeks. (xv) Participants with contractures were treated accordingly. (xvi) Neuromuscular facilitation techniques. (xvii) Gait training. (xviii) Stair practice (up and down)" The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising functional task training, modality, musculoskeletal intervention (active), musculoskeletal intervention (passive) and neurophysiological intervention Length of intervention period: 30 days Number of sessions and length of individual sessions: each session lasting at least 45 minutes, one/d Intervention provider: "one to one sessions with a therapist" (2) Control group (n = 25)
	Participants in the control group received routine treatment (such as medicine) only The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising no treatment Length of intervention period: no intervention Number of sessions and length of individual sessions: no intervention Intervention provider: no intervention This study is classified as intervention (functional task training, musculoskeletal (active) , musculoskeletal (passive), neurophysiological) versus no treatment (Table 4). The in-
	tervention group also received modality
Outcomes	Measures of Independence in ADL: Modified Barthel index Measures of motor function: simplified Fugl-Meyer Other secondary outcome measures: cognitive ability rating (translated) Time points when outcomes were assessed: at enrolment and 30 days after enrolment
Notes	Original study translated from Chinese to English

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Stratified randomisation done, randomisa- tion done by participants' onset of stroke
Allocation concealment (selection bias)	Unclear risk	Insufficient details
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Outcome assessors did not deliver interven- tion and were blinded to group allocation
Incomplete outcome data (attrition bias) All outcomes	Unclear risk	No dropouts reported

Free of systematic differences in baseline characteristics of groups compared?	Low risk	No obvious difference between groups for time since stroke, gender, age, side and type of stroke, etc
Did authors adjust for baseline differences in their analyses?	Low risk	No information provided
Other bias	Unclear risk	No information provided
Hui-Chan 2009		
Methods	Study design: "single-blinded, randomised, Method of randomisation: "subjects were all	placebo-controlled trial" ocated randomly, using a computer program"
Participants	Number of participants: n = 54 (109 in whole study-but only 54 in groups relevant to this review: see notes) Inclusion criteria: "sustained a single stroke more than 1 year previously, were able to walk 10 m unassisted, with or without walking aids, and had a Composite Spasticity Score of \geq 10 in their ankle plantarflexors" Exclusion criteria: "medical comorbidity, e.g. unstable cardiopulmonary disease (acute myocardial infarction, wearing a cardiac pacemaker, shortness of breath, tachycardia), uncontrolled diabetes mellitus, or pre-existing neurological disorders such as multiple sclerosis, receptive dysphasia, or cognitive impairment (denoted by scoring < 7 out of 10 on the Abbreviated Mental Test)"	
Interventions	 (1) PLBO + TRT group (n = 25) "received 60 minutes of placebo-TENS from TENS devices with the electrical circuit disconnected inside, followed by 60 minutes of TRT which included six exercises: (i) loading exercise on the affected leg, (ii) stepping up exercise with the affected leg, (iii) stepping down exercise with the unaffected leg, (iv) heel lifts from a dorsiflexed position when standing, (v) standing up from a chair, walking a short distance, and returning to the chair, and (vi) walking with rhythmic auditory cues generated by a metronome" The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising functional task training Length of intervention period: four weeks Number of sessions and length of individual sessions: "home rehabilitation programme daily, 5 days a week" Intervention provider: "The treatment compliance and safety of the programme [were] closely monitored by the physiotherapist in charge" (2) Control group (n = 29) "received no treatment" The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as no intervention Length of intervention period: no intervention Length of intervention period: no intervention Length of intervention period: no intervention 	

Hui-Chan 2009 (Continued)

Outcomes	Measures of postural control and balance: Timed Up and Go (TUG) test Measures of voluntary movements: gait velocity, Six-Minute Walk test Measures of tone and spasticity: Composite Spasticity Scale Other secondary outcome measures: surface electromyography and torque measurements Time points when outcomes were assessed: "assessor blinded to the treatment allocation assessed the subjects at four time intervals: before and after 2 and 4 weeks of treatment, and 4 weeks after treatment"
Notes	This study also included a TENS group $(n = 28)$ and a TENS + TRT group $(n = 27)$ that we judged not to be relevant to this review, and no data relating to these groups have been extracted

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	"subjects were allocated randomly, using a computer program"
Allocation concealment (selection bias)	Unclear risk	No information provided
Blinding of outcome assessment (detection bias) All outcomes	Low risk	"assessor blinded to the treatment alloca- tion assessed the subjects at four time in- tervals"
Incomplete outcome data (attrition bias) All outcomes	Unclear risk	"Eight (7.3 %) subjects dropped out from the study" (NB: This is eight of the whole study size of 109.) Reasons for, or groups of, dropouts were not reported
Free of systematic differences in baseline characteristics of groups compared?	Low risk	"No significant differences were found be- tween the groups in the five baseline out- come measurements (age, gender, weight, height, and the type, side and duration of their strokes)"
Did authors adjust for baseline differences in their analyses?	Low risk	No information provided
Other bias	Unclear risk	No information provided

Jiang 2006

Methods	Study design: RCT Method of randomisation: stratified randomisation
Participants	Number of participants: n = 82 (baseline data available); n = 79 (data extraction at six months) Inclusion criteria: "According to the evaluative standard revised by the 1995 Fourth National Academic Conference of Cerebral Vascular Disease, ischaemic and haemorrhagic stroke were diagnosed, confirmed by CT or MRI scan, willingly signed informed consent forms, medically stable within a week, Glasgow Coma Score > 8, aged between 40 to 80 years and possessed deficits in limb function" Exclusion criteria: "Active liver disease, impaired liver or kidney function, cardiovascular conditions, malignant tumours, history of cognitive issues, impaired respiratory function, paralysis of four limbs; ischaemic or haemorrhagic stroke exceeding 3 weeks, pre-existing cerebral vascular disease resulting in functional deficits, unable to manage home visits, psychological conditions and deafness and/or muteness"
Interventions	(1) Treated group (n = 42) "Enrolled patients were classed by infarct cerebral accident (ICA) or hemorrhagic cerebral accident (HCA), and randomised into treated or control group" "From stroke onset to 1 month after stroke, during stage 1 rehabilitation, the patients in the treated group mainly had treatment in the Department of Neurology ward, and while being given usual medical treatment in the Department of Neurology were given early bed side rehabilitation therapy once medically stable, and commenced rehabilitation therapy 1 week after the patient's symptoms stabilised; from the second month after stroke to the end of the third month after stroke (stage 2 rehabilitation), and from the fourth month after stroke to the end of the sixth month after stroke (stage 3 rehabilitation), patients were transferred to the rehabilitation ward/centre for continued treatment depending on the patient's condition and functional recovery status, or tansferred to home, where therapists would guide and assist patients in undertaking the necessary functional training, until the end of follow-up. Here, 'stage one rehabilitation' refers to patient's early stage energency visit to hospital or conventional medicine treatment as well as early stage rehabilitative treatment, 'stage two rehabilitation' refers to patient's rehabilitative treatment method combined physiotherapy (PT) and occupational therapy (OT) into a holistic method. Stage one rehabilitation included anti-spasticity positioning, passive training of limbs, active training of non-affected limbs under guidance, deep breathing as well as training of abdominal muscles, sitting up from lying, sitting balance and standing up training etc, in order to tanih the patient's ability to get up from the bed, (treatment is done) 1/day, 45 min/session, 5/week, during the training period, the patient's family or nursing workers were taught the correct supplementary exercises and methods of care concurrently, in order to achieve partial training out with therapy times, while also re

tation within rehabilitation ward/centre, was delivered by therapists, while concurrently teaching patient's family or nursing workers how to assist the patient in training; some patients during the second stage community rehabilitation had therapists conducting home visits to provide guidance on rehabilitation treatment 1/week, teaching patient's family or nursing workers how to assist the patient in training while treating the patient, leaving them to assist the patient to complete the remaining bulk of the training in the week; during stage three community rehabilitation, therapists conducted fortnightly home visits, and while delivering occupational therapy and necessary physiotherapy, also taught the patient in completing the remaining daily necessary training"

The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising functional task training, modality and musculoskeletal intervention (passive)

Length of intervention period: six months

Number of sessions and length of individual sessions: "stage one rehabilitation-1/day, 45 min/session, 5 x/week; stage two rehabilitation-2/day, 30 - 45 min/session, 5 x/week and stage three rehabilitation- 2/day, 30 - 45 min/session, 5 - 7 days/week"

Intervention provider: "Stage one early rehabilitation and stage two rehabilitation within rehabilitation ward/centre, was delivered by therapists, while concurrently teaching patient's family or nursing workers how to assist the patient in training; some patients during the second stage community rehabilitation had therapists conducting home visits to provide guidance on rehabilitation treatment 1x/week, teaching patient's family or nursing workers how to assist the patient in training while treating the patient, leaving them to assist the patient to complete the remaining bulk of the training in the week; during stage three community rehabilitation, therapists conducted fortnightly home visits, and while delivering occupational therapy and necessary physiotherapy, also taught the patient's family or nursing workers how to help the patient train, leaving them to assist the patient in completing the remaining daily necessary training" (2) Control group (n = 40)

"Patients in the control group were not given standardised rehabilitation therapy, but were given the same usual medical treatment as the treated group. It was noted that some patients self-trained after verbal advice from their doctor, while some patients' families assisted the patient in movement based on their own knowledge, and the possibility that some patients underwent certain rehabilitation treatment after seeking help from other rehabilitation organisations upon discharge cannot be excluded"

The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising no treatment

Length of intervention period: not stated Number of sessions and length of individual sessions: not stated Intervention provider: not stated

This study is classified as intervention (functional task training, musculoskeletal (passive)) versus no treatment (Table 4). The intervention group also received modality

Outcomes	Functional Comprehensive Assessment (FCA) Time points when outcomes were assessed: at enrolment, six months after stroke
Notes	Original study translated from Chinese to English No data suitable for analysis

Risk of bias

KISR OJ DIAS		
Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Stratified randomisation
Allocation concealment (selection bias)	Unclear risk	No information provided
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Outcome assessor did not deliver interven- tion and was blinded to group allocation
Incomplete outcome data (attrition bias) All outcomes	Low risk	Dropouts accounted for (only three drop- outs)
Free of systematic differences in baseline characteristics of groups compared?	Low risk	No obvious difference between groups for time since stroke, gender, age, side and type of stroke, etc
Did authors adjust for baseline differences in their analyses?	Low risk	No information provided
Other bias	Unclear risk	It was noted that some participants self- trained after receiving verbal advice from their doctor, while some participants' fam- ilies assisted the participant in movement based on their own knowledge, and the pos- sibility that some participants underwent certain rehabilitation treatment after seek- ing help from other rehabilitation organi- sations upon discharge cannot be excluded

Jing 2006

Methods	Study design: RCT Method of randomisation: "Randomisation done using SPSS 12.0 software"
Participants	Number of participants: n = 160 Inclusion criteria: "(1) Stroke diagnosis according to the evaluative standard revised by the 1995 Fourth National Academic Conference of Cerebral Vascular Disease; (2) confirmed by CT or MRI scan; (3) first ever stroke, within 3 months of stroke; (4) cognitively sound, able to cooperate, understood and agreeable to intervention" Exclusion criteria: "incomplete patient information, huge lapses in memory loss"
Interventions	(1) Exercise and occupational therapy group (n = 120) "For the exercise + occupational therapy participants, while following the principles of

	the intervention of the exercise therapy group, the following intervention was done: early rolling, donning, feeding, transfers etc and re-learning and practising ADL activities, focusing on activities of choice for therapy, focusing on the dexterity of affected limbs, through active and active-assisted means of training, and compensating with the non-affected limb training etc. Emphasised on activities with the largest ADL limitation. In the ward, patient's family and nurse supervised ADL activities, rendering as little assistance as possible. 45-60 min/day, one to one therapy session with an occupational therapist" The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising functional task training, musculoskeletal intervention (passive) and neurophysiological intervention
	Length of intervention period: not stated
	Number of sessions and length of individual sessions: 45 to 60 minutes/d
	Intervention provider: occupational therapist (2) Exercise therapy group (n = 40)
	"For the exercise therapy participants, after becoming medically stable, while concur- rently receiving conventional treatment, had the following intervention: positioning of
	the unaffected limbs, passive ranging exercises of the joints, bridging exercises, neuro-
	muscular facilitation technique, sitting balance, standing balance and gait training etc" The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising functional task training, musculoskeletal intervention (passive) and neurophysiological intervention Length of intervention period: on average seven weeks Number of sessions and length of individual sessions: 40 to 50 minutes/d Intervention provider: one-to-one therapy session with an exercise therapist This study is classified as active intervention one (functional task training, musculoskele- tal (active), musculoskeletal (passive), neurophysiological) versus active intervention two (functional task training, musculoskeletal (passive), neurophysiological) (Table 6)
Outcomes	Measures of Independence in ADL: Barthel Index Measures of motor function: Fugl-Meyer Assessment Time points when outcomes were assessed: within 24 hours of commencement of therapy, every two weeks thereafter
Notes	Original study translated from Chinese to English As the two active treatment groups were classified as including similar treatment com- ponents, data from this study have not been included within the comparisons of one active intervention versus another active intervention
Pick of high	

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	"Random number generation using SPSS 12.0 software." No reason is provided for the unequal distribution between groups (120 and 40)

Allocation concealment (selection bias)	Unclear risk	No information provided
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Blind assessment
Incomplete outcome data (attrition bias) All outcomes	Unclear risk	No dropouts reported
Free of systematic differences in baseline characteristics of groups compared?	Low risk	No obvious difference between groups for time since stroke, gender, age, side and type of stroke
Did authors adjust for baseline differences in their analyses?	Low risk	No information provided
Other bias	Unclear risk	No information provided
Kim 2011		
Methods	Study design: RCT Method of randomisation: not stated "40 patients diagnosed with hemiplegia due to stroke were randomly assigned"	
Participants	Number of participants: n = 40 Inclusion criteria: "The study subjects were selected from among patients diagnosed with stroke who could walk by themselves without being helped by others or could walk at least 10 m using a walking aid, scored at least 24 points in the mini-mental state examination-K (MMSE-K), had spasticity of Grade 2 or lower in the affected lower extremity as evaluated by the Modified Ashworth Scale (MAS), had no orthopaedic problem that could affect the treatment, and could receive training for 30 minutes or longer"	
Interventions	 (1) PNF group (n = 20) "Trunk stability exercise using proprioceptive neuromuscular facilitation (PNF)" "The experimental group received therapeutic intervention of PNF using SR and RS for 10 minutes during 30 minutes of general therapeutic exercise, implemented five times a week for six weeks" "The PNF provided to the experimental group was implemented after the exercise programs were explained and demonstrated by professionally trained therapists so that the subjects would sufficiently understand the exercise programs" The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising musculoskeletal (active), musculoskeletal (passive) and neurophysiological intervention Length of intervention period: six weeks Number of sessions and length of individual sessions: "intervention of PNF using SR (stabilising reversal) and RS (rhythmic stabilisation) for 10 minutes during 30 minutes of general therapeutic exercise, implemented five times a week" 	

	 Intervention provider: "professionally trained therapists" (2) Control group (n = 20) "The control group received only general therapeutic exercise for 30 minutes, five times a 	
	week for six weeks. The general therapeutic exercise was composed of stretching exercise and exercises for the range of motion of joints"	
	The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising musculoskeletal intervention (active) and musculoskeletal intervention (passive) Length of intervention period: six weeks Number of sessions and length of individual sessions: 30 minutes, five times a week Intervention provider: not stated This study is classified as active intervention one (musculoskeletal (active), musculoskele- tal (passive), neurophysiological) versus active intervention two (musculoskeletal (active) , musculoskeletal (passive)) (Table 6)	
Outcomes	Measures of postural control and balance: Functional Reach Test (FRT) Other secondary outcome measures: EMG measures of four muscles (soleus, tibialis anterior, hamstring, quadriceps) Time points when outcomes were assessed: "pre- and post-experiment measurements were made of the FRT"

Kim 2012

Methods	Study design: RCT Method of randomisation: not stated ("participants were randomly assigned to two groups")
Participants	Number of participants: n = 20 Inclusion criteria: "ability to walk 10 m independently using an aid or orthotic with or without supervision or aid, and minimum score of 20 in the Korean Mini-Mental State Examination (K-MMSE)" Exclusion criteria: "joint contraction, pain or fracture of the musculoskeletal system, and hemianopsia"
Interventions	 (1) Experimental group (n = 10) "Subjects in both groups underwent conservative physical therapy" "The experimental group also participated in task-oriented training for 1 hour per day, 3 days a week, for 4 weeks. The training consists of 10 walking-related tasks designed to strengthen the lower extremities, and enhance the walking balance, speed and distance in a progressive manner. The 10 tasks were (i) step-ups, (ii) balance beam, (iii) kicking a ball, (iv) stand up and walk, (v) obstacle course, (vi) treadmill, (vii) walk and carry, (viii) speed walk, (ix) walk backwards, and (x) stairs. Before commencing training, the subjects warmed up for 5 minutes to improve their range of motion and flexibility. Each item was practiced for 5 minutes, and 1 minute of rest time was allowed between each item" The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising functional task training, musculoskeletal intervention (active) and musculoskeletal intervention (passive) Length of intervention period: four weeks Number of sessions and length of individual sessions: conservative physical training for one hour per day, five days a week. in addition to task-oriented training for one hour per day, three days per week Intervention provider: "supervised by a physical or occupational therapist" (2) Control group (n = 10) "Conservative physical therapy consisted of joint mobilization, muscle strengthening, and balance training" The individual components delivered are listed in Table 3. Based on the individual components, this intervention (active) and musculoskeletal intervention (passive)) Length of intervention period: four weeks Number of sessions and length of individual sessions: conservative physical training for one hour per day, five days a week Intervention provider: not stated This study is classified as
Outcomes	Measures of postural control and balance: Berg Balance Scale, Timed-Up and Go test (TUG),Trunk Impairment Scale Measures of voluntary movements: 10-Metre Walk test Time points when outcomes were assessed: "measured before and after the 4 weeks of therapy"

Notes

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	"participants were randomly assigned to two groups"
Allocation concealment (selection bias)	Unclear risk	No information provided
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	No information provided
Incomplete outcome data (attrition bias) All outcomes	Unclear risk	No dropouts reported
Free of systematic differences in baseline characteristics of groups compared?	Unclear risk	Limited baseline demographics Pretraining outcome measures similar across groups except on the TUG test
Did authors adjust for baseline differences in their analyses?	Unclear risk	No information provided
Other bias	High risk	Although both groups received active in- terventions, the dose was substantially less for the second group

Kwakkel 2002

Methods	Study design: RCT with three treatment groups Method of randomisation: "within the first 14 days poststroke, patients were randomly assigned to one of the 3 treatment conditions. Randomisation (permuted blocks of 9), with random number tables for every participating hospital, was applied"
Participants	Number of participants: n = 53 Inclusion criteria: "Primary, first-ever stroke in the territory of the middle cerebral artery as revealed by CT or MRI, aged between 30 to 80 years, impaired lower extremities (LE) and upper extremities (UE) motor function as assessed with the Motricity Index (i.e. scores < 100 points for each paretic limb), unable to walk without assistance on admission, no complicating medical history on the basis of review of medical records such as cardiac, pulmonary or neurological disorders. No severe deficits in communication, memory, or understanding and gave written or verbal informed consent and were sufficiently motivated to participate"

standing balance. In addition, in interlimb coordination dur "The guidelines were based o reported in 165 intervention we believe is an eclectic appro- motor skills needs to be both The individual components components, this intervention Length of intervention perio onward, type of treatment and and occupational therapists in Number of sessions and length a week. In addition, all three of 15 minutes of LE exercises minute session of ADL trainii Intervention provider: physic. (2) Upper extremities (UE) gg "focused on the improvement combing" The individual components components, this intervention Length of intervention perio onward, type of treatment and and occupational therapists in Number of sessions and length a week. In addition, all three of 15 minutes of LE exercises minute session of ADL trainii Intervention perio onward, type of treatment and and occupational therapists in Number of sessions and length a week. In addition, all three of 15 minutes of LE exercises minute session of ADL trainii Intervention provider: physicz (3) Control group (n = 18) "Immobilisation of the paret which was applied for 30 min The individual components components, this intervention Length of intervention perio onward, type of treatment and and occupational therapists in Number of sessions and length a week. We used what oach based on research indicating that subjects' practice of task and context specific" delivered are listed in Table 3. Based on the individual n is categorised as comprising functional task training od: for a period of 20 weeks post stroke ("from week 20 d its duration [were] determined by the physical therapists nvolved, on average 3 times half an hour a week") h of individual sessions: 30 minutes of LE training, five days groups participated daily in a basic treatment programme es and 15 minutes of UE exercises, as well as a weekly 90- ing administered by an occupational therapists cal therapists and occupational therapists
---	--

Kwakkel 2002 (Continued)

Outcomes	Measures of voluntary movements: comfortable and maximal walking speeds Other secondary outcome measures: mean continuous relative phase Time points when outcomes were assessed: "patients were assessed during the first 10 weeks on a weekly basis and biweekly from week 10 to week 20. With exception of kinematic measurements, final assessment took place at 26 weeks poststroke"
Notes	Intervention two comprised upper limb training. Although upper limb training might be classed as a subcomponent of functional task training, for the purposes of comparisons in this review we have categorised this intervention as an attention control. This is because the upper limb training was delivered alone (i.e. no other subcomponents of functional task training were delivered), and therefore no active treatment was aimed at lower limb or balance outcomes No outcomes included in analysis because it was unclear at which time points the data were collected

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	"Randomisation (permuted blocks of 9), with random number tables for every par- ticipating hospital, was applied"
Allocation concealment (selection bias)	Low risk	"Concealed allocation was done by the use of sealed envelopes"
Blinding of outcome assessment (detection bias) All outcomes	Low risk	All measurements were carried out by an independent observer who had more than 15 years of experience in the use of these measurement instruments
Incomplete outcome data (attrition bias) All outcomes	Low risk	No dropouts
Free of systematic differences in baseline characteristics of groups compared?	Low risk	"No differences in subject characteristics were found amongst the 3 treatment groups at either the time of onset or the first gait assessment"
Did authors adjust for baseline differences in their analyses?	Low risk	No systematic differences
Other bias	Unclear risk	No information provided

Kwakkel 2008

Methods	Study design: RCT Method of randomisation: "Participants were stratified by rehabilitation centre, and randomisation took place using an 'online' minimisation procedure"
Participants	Number of participants: n = 250 Inclusion criteria: verified stroke according to the WHO definition, able to walk a minimum of 10 m without physical assistance (functional ambulation categories \geq three) , discharged home from a rehabilitation centre, needed to continue physiotherapy during outpatient care to improve walking competency or physical condition, or both, able to give informed consent and be motivated to participate in a 12-week intensive programme of physiotherapy Exclusion criteria: cognitive deficits as evaluated by the mini-mental state examination (< 24 points), unable to communicate (< four points on the Utrechts Communicatie Onderzoek, UCO) and lived farther than 30 km from the rehabilitation centre
Interventions	 (1) Circuit training (n = 126) "Graded task oriented circuit training programme ('warming up (5 minutes), circuit training (60 minutes), evaluation and a short break (10 minutes), and group game (15 minutes)') twice a week over a 12 week period (24 sessions)" "Training included eight different workstations, intended to improve meaningful tasks relating to walking competency" The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising functional task training and musculoskeletal intervention (active) Length of intervention period: 12 weeks Number of sessions and length of individual sessions: "90 minute session twice a week (24 sessions). The circuit training group received 4461 treatment sessions, average treatment time per session was 72 (SD 39) minutes" Intervention provider: physiotherapist and sports therapist (2) Usual physiotherapy (n = 124) "Patients allocated to the control group received usual outpatient physiotherapy, mainly one to one treatments tailored to the patient with a physical condition, and walking competency were provided according to Dutch physical condition, and walking competency were provided according to Dutch physiotherapy guidelines" The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising usual care (cardiopulmonary intervention, functional task training and musculoskeletal intervention (active)) Length of intervention period: not stated Number of sessions and length of individual sessions: "no additional restrictions with respect to content, time, or duration of the physiotherapy. The group received 4378 with an average of 34 (SD 10) minutes per session" Intervention provider: physiotherapist This study is classified as intervention (functional task training, musculoskeletal (active)) (Table 5)
Outcomes	Measures of motor function: Rivermead Mobility Index (RMI) Measures of postural control and balance: timed balance test, Timed Up and Go, mod- ified stairs test

Kwakkel 2008 (Continued)

	Measures of voluntary movements: Six-Minute Walk test, five-metre comfortable walking speed test, functional ambulation categories Measures of participation: Nottingham extended activities of daily living (NEADL) Other secondary outcome measures: Stroke Impact Scale, Falls Efficacy Scale (FES), Hospital Anxiety and Depression Scale (HADS), Fatigue Severity Scale (FSS), Letter cancellation task, the Motricity index (MI-arm and MI-leg) Time points when outcomes were assessed: "measured all outcomes before randomisation at baseline and after 12 and 24 weeks"
Notes	Full details of this trial, called FIT-Stroke, have been reported elsewhere (see Van de Port, I, Wevers L, Roelse H, van Kats L, Lindeman E, Kwakkel G. Cost-effectiveness of a structured progressive task-oriented circuit class training programme to enhance walking competency after stroke: the protocol of the FIT-Stroke trial. BMC Neurol 2009;9:43, for more details on trial methodology and randomisation)

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	"Patients were randomly allocated to cir- cuit training or usual physiotherapy, after stratification by rehabilitation centre, with an online randomisation procedure"
Allocation concealment (selection bias)	Unclear risk	Not stated
Blinding of outcome assessment (detection bias) All outcomes	Low risk	"Three trained research assistants (LW, HK, LK), who were blinded to treatment allo- cation, measured all outcomes before ran- domisation at baseline and after 12 and 24 weeks in face to face meetings at the pa- tient's own home or at the rehabilitation centre"
Incomplete outcome data (attrition bias) All outcomes	Low risk	Dropouts accounted for "Of the 250 included patients, one patient in the circuit training group and seven in the usual care group were excluded from the analysis. Reasons were withdrawal from participation (n=3), death from cancer (n= 2), and recurrent stroke (n=2), while one patient missed the 12 week assessment visit because of change of address. No patients were lost to follow-up after 12 weeks"
Free of systematic differences in baseline characteristics of groups compared?	Unclear risk	Significant baseline differences in favour of the circuit training group for a few sec- ondary outcomes

Did authors adjust for baseline differences in their analyses?	Low risk	Significant baseline differences in favour of the circuit training group for a few sec- ondary outcomes. All analyses, however, were adjusted for these co-variates at base- line
Other bias	Unclear risk	"Patients with only mild to moderate stroke were selected, which limits the generalis- ability of our trial. Able to recruit only a quarter of all patients who were discharged from one of the participating rehabilitation centres. These centres receive about 10% of all patients with stroke discharged from hospitals in the Netherlands. About a third of all patients discharged from these reha- bilitation centres showed no or insufficient problems with walking and another third were too ill to be included in the present study" "The combination of workstations in FIT- Stroke represents an arbitrary selection. Our workstations were selected for safety, clinical relevance in terms of activities, sim- plicity of execution, and feasibility, with- out additional costs to the physiotherapy department. Unclear whether a different combination of workstations would have resulted in other outcomes. In our opinion, the workstations for task oriented circuit training should at least be task specific, in- tensive, and graded in time"

Langhammer 2000

Methods	Study design: RCT Method of randomisation: double-blind randomisation (stratified according to sex and side of lesion) and sealed coding
Participants	Number of participants: n = 61 Inclusion criteria: first stroke, verified clinically and by CT scan, no subarachnoid bleed- ing, no tumours, no severe medical conditions and not more than four points on each MAS section
Interventions	 (1) Neurophysiological (Bobath) (n = 28) A "theoretical framework in a reflex-hierarchical theory" Physiotherapists attended workshops and discussed the treatment approaches and were provided with a manual, based on the supporting texts, which described the key philosophy of the approaches

Langhammer 2000 (Continued)

	lechniques were not described
	The individual components delivered are listed in Table 3. Based on the individual com-
	ponents, this intervention is categorised as comprising neurophysiological intervention
	Length of intervention period: "as long as they were hospitalized"
	Number of sessions and length of individual sessions: five days/wk for a minimum of
	40 minutes, while an inpatient. Folowing discharge, attempts were made to ensure that
	physiotherapy continued based on the assigned approach, and physiotherapists involved
	in the treatment were able to discuss treatments with hospital physiotherapists and project
	leaders
	Intervention provider: physiotherapists
	(2) Motor learning $(n = 33)$
	"Based in system theory, and is basically task-oriented"
	Physiotherapists attended workshops and discussed the treatment approaches and were
	provided with a manual, based on the supporting texts, that described the key philosophy
	of the approaches
	Techniques were not described
	The individual components delivered are listed in Table 3. Based on the individual
	components, this intervention is categorised as comprising functional task training
	Length of intervention period: "as long as they were hospitalized"
	Number of sessions and length of individual sessions: as above
	Intervention provider: physiotherapists
	This study is classified as active intervention one (neurophysiological) versus active in-
	tervention two (functional task training) (Table 6)
Outcomes	Measures of Independence in ADL: Barthel Index
	Measures of functional independence: MAS; Sodring Motor Evaluation
	Other secondary outcome measures: Nottingham Health Profile
	Other secondary outcome measures: length of stay, use of assistive devices, discharge
	destination
	Time points when outcomes were assessed: "patients were tested three times: (1) three
	days after admission to the hospital, (2) two weeks thereafter, and (3) three months post
	stroke"

Notes

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Double-blind randomisation (stratified ac- cording to sex and side of lesion) and sealed coding
Allocation concealment (selection bias)	Low risk	"The study was double blind, and the code was sealed until the last test was performed at three months follow-up"

Langhammer	2000	(Continued)
------------	------	-------------

Blinding of outcome assessment (detection bias) All outcomes	Low risk	Unclear whether the participant was blinded Therapist was not blinded ("Information concerning the physiotherapy used was known only by the therapists who treated the patients and the secretary of the ward, who was in charge of the randomization") Assessor was blinded ("The tests were con- ducted by the project leader who had no information about which group the patient belonged to")
Incomplete outcome data (attrition bias) All outcomes	Low risk	Dropouts accounted for 29/33 in motor learning group and 24/28 in Bobath group completed intervention
Free of systematic differences in baseline characteristics of groups compared?	Low risk	"Mean age of the patients was 78 years (range 49-95 years, SD 9), with no signif- icant difference between the two groups. Marital status was also similar" "There were no significant differences in MAS, SMES or Barthel ADL Index be- tween the two groups in the acute stage"
Did authors adjust for baseline differences in their analyses?	Low risk	No information provided
Other bias	Unclear risk	The same therapists provided treatment to participants in both treatment groups, cre- ating the possibility of contamination be- tween groups. Treatment following hospi- tal discharge may not have been adminis- tered according to the randomisation pro- cess, potentially introducing performance bias to the postdischarge results

Methods	Study design: "longitudinal randomized controlled stratified trial" Method of randomisation: "At discharge from the acute hospital, patients were random- ized to one of two different groups by a person not involved with the patients or the treatment in the ward. Randomization was performed with a die: patients with uneven numbers went to group 1, an intensive exercise group, and those with even numbers to group 2, a regular exercise group. Stratification was according to gender and hemisphere lesion: the first male patient with a right hemisphere lesion and with an uneven number was allocated to the intensive exercise group, and the next male patient with a right hemisphere lesion was allocated to the regular exercise group. The procedure with the die was then used when the third male patient with a right hemisphere lesion entered the stroke unit and so on. A corresponding procedure was followed for female patients"
Participants	Number of participants: n = 75 Inclusion criteria: "Inclusion criteria were first-time-ever stroke with neurological signs, computer tomography-confirmed stroke and voluntary participation" Exclusion criteria: "more than one stroke incident, subarachnoid bleeding, tumour, other serious illness, and brainstem or cerebellar stroke"
Interventions	 (1) Intensive exercise (n = 35) "The subsequent training for the intensive exercise group included a functional exercise programme with emphasis on high intensity of endurance, strength and balance. The individualized training programmes were aimed at functional improvements but with variations, for example: getting up from a chair, walking indoors, Nordic walking outdoors, stationary bicycling, and stair walking, where the physiotherapist monitored the levels of intensity through Borg's Scale or through the pulse rate. A protocol with suggestions of types of exercises and levels of intensity was developed in discussion with all physiotherapists involved. This protocol was intended as a guideline. The goal of these exercises was to improve and maintain motor function, activities of daily living and grip strength. Patients in the intensive exercise group were also encouraged to maintain a high activity level apart from that in the training sessions" The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising cardiopulmonary intervention, functional task training and musculoskeletal intervention (active) Length of intervention period: 12 months Number of sessions and length of individual sessions: "Arrangements were made for patients allocated to the intensive exercise group to have physiotherapy during four periods, with a minimum of 20 hours every third month, in the first year after the stroke. The intervention sessions started immediately after discharge, two or three times a week if the patient was at home or attending a private physiotherapy practice, and daily if he or she was in a rehabilitation ward. This intervention was repeated after three months, six months and one year" Intervention provider: physiotherapists (2) Regular exercise (n = 40) "If the patients in the regular exercise group were considered to be in need of follow-up treatment or rehabili

Langhammer 2007 (Continued)

	components, this intervention is categorised as comprising usual care Length of intervention period: 12 months Number of sessions and length of individual sessions: "The regular exercise group pa- tients were given follow-up treatment according to their needs, as considered by the rehabilitation staff at the stroke unit/rehabilitation department and by the rehabilitation team in the community after discharge" Intervention provider: physiotherapists This study is classified as active intervention one (functional task training, musculoskele- tal (active)) versus usual care (Table 5). The intervention group also received cardiopul- monary intervention
Outcomes	Measures of independence in ADL: Barthel index Measures of motor function: motor assessment scale Other secondary outcome measures: grip strength Time points when outcomes were assessed: "patients were tested on admission, at dis- charge, and three months, six months and one year after stroke by an experienced inves- tigator, blinded to group allocation"
Notes	During the acute phase of rehabilitation at the hospital, both groups received functional task-oriented training tailored to their specific needs. The amount of training was equal in the two groups, with two periods per day, the two periods comprising a total of one hour of physiotherapy in combination with other specialised therapies according to the participant's needs. At discharge, participants were randomly assigned to two separate groups-an intensive exercise group and a regular exercise group, as described above

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	"Randomization was performed with a die: patients with uneven numbers went to group 1, an intensive exercise group, and those with even numbers to group 2, a reg- ular exercise group. Stratification was ac- cording to gender and hemisphere lesion: the first male patient with a right hemi- sphere lesion and with an uneven num- ber was allocated to the intensive exercise group, and the next male patient with a right hemisphere lesion was allocated to the regular exercise group. The procedure with the die was then used when the third male patient with a right hemisphere lesion en- tered the stroke unit and so on. A corre- sponding procedure was followed for fe- male patients"

Langhammer 2007 (Continued)

Allocation concealment (selection bias)	Low risk	"At discharge from the acute hospital, pa- tients were randomized to one of two dif- ferent groups by a person not involved with the patients or the treatment in the ward"
Blinding of outcome assessment (detection bias) All outcomes	Low risk	The protocol was sealed for 1.5 years from the start of the study until the last included participant was tested at one year of follow- up. The study was an intention-to-treat trial with the aim of being double-blind, that is, neither the investigator nor the par- ticipants knew to which group participants were allocated
Incomplete outcome data (attrition bias) All outcomes	Low risk	Dropouts accounted for Of these 75 initially included in the study, four died and four withdrew during the acute stage
Free of systematic differences in baseline characteristics of groups compared?	Low risk	"no significant differences between the groups regarding age, hemisphere lesion, marital status at baseline, or admission to the stroke unit"
Did authors adjust for baseline differences in their analyses?	Unclear risk	No information provided
Other bias	Unclear risk	No information provided
Lennon 2006		
Methods	Study design: RCT Method of randomisation: "after giving informed consent, patients were randomised using sealed envelopes"	
Participants	Number of participants: n = 61 Inclusion criteria: "All consecutive patients within 8 to 14 days poststroke were included if medically stable with a first-ever stroke and they were able to stand or walk with assistance"	
Interventions	 (1) Bobath group (n = 30) "Conventional Bobath therapy" The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising neurophysiological intervention Length of intervention period: four weeks Number of sessions and length of individual sessions: five sessions/wk (total of 20 sessions) lasting 40 minutes Intervention provider: not stated 	

Lennon 2006 (Continued)

	 (2) Gait-specific group (n = 31) "introducing more walking practice into Bobath therapy (spending 50% of the daily physiotherapy session working on walking practice)" The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising functional task training and neurophysiological intervention Length of intervention period: four weeks Number of sessions and length of individual sessions: five sessions/wk (total of 20 sessions) lasting 40 minutes Intervention provider: not stated This study is classified as active intervention one (neurophysiological) versus active intervention two (functional task training, neurophysiological) (Table 6)
Outcomes	Measures of Independence in ADL: Barthel Index Measures of motor function: Motor Assessment Scale, modified Rivermead Mobility Index Measures of postural control and balance: Step test Measures of voluntary movements: 10-Metre Walk test Time points when outcomes were assessed: "All measures were performed by a blinded assessor at baseline, post intervention, at 3 and 6 months post stroke"
Notes	Abstracts only Data not suitable for analysis

Methods	Study design: RCT Method of randomisation: not stated
Participants	Number of participants: n = 61 Inclusion criteria: "Satisfied 1986 2nd National Conference of Cerebral Vascular Disease assessment guidelines and confirmed by CT or MRI scan of ischaemic or haemorrhagic stroke"
Interventions	 (1) Early rehabilitation group (n = 30) "Basic treatment for the two groups: use of medication to prevent cerebral oedema during the acure phase, dosage and time dependent on the medical condition. In addition, the early rehabilitation group used Bobath technique for training. Commencement of training: ischaemia, between 24 hours and 8 days after stroke onset; medically stable. Main method of rehabilitation was as follows: (1) supine: (1) maintain anti-spasticity positions, with regular positional change. ii) Passive ranging of all joints. iii) Active rolling, moving. iv) Bridging exercise training. v) Truncal movement training, vi) Independently complete transfer from supine to sitting up. (II) Sitting: (i) Crawling or kneeling position training. (ii) Sitting balance training - 3 stages. (iii) Independently complete transfer from sitting to standing up. (III) Standing balance training: In standing, while loading onto the affected lower limb, step forward and backward in increasing amount of angle with the non-affected lower limb. Without extending the hip, move the knee forward, dorsiflex ankle, and heel strike" The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising functional task training, musculoskeletal intervention provider: not stated (2) Control group (n = 31) "Basic treatment for the two groups: use of medication to prevent cerebral oedema during the acure phase, dosage and time dependent on the medical condition. Control group did not have rehabilitor practice" The individual components delivered are listed in Table 3. Based on the individual components, this intervention period: one month Number of sessions and length of individual sessions: "noon and afternoon/daily, 30 min/session" Intervention provider: not stated (2) Control group (n = 31) "Basic treatment for the two groups: use of medication to prevent cerebral oedema du
Outcomes	Measures of Independence in ADL: Barthel Index Measures of motor function: Fugl-Meyer Assessment Other secondary outcome measures: neurological deficit score Time points when outcomes were assessed: before rehabilitation practice and after one month of intervention

Li 2003 Methods Study design: RCT Method of randomisation: not stated ("Total 174 patients were selected in this study, and these patients were randomly divided") Participants Number of participants: n = 174 Inclusion criteria: not stated ("359 patients with paralysis after cerebral hemorrhage were admitted from March 2001 to May 2002") Interventions (1) Rehabilitation group (n = 87)"received regular nursing and rehabilitation nursing" "In the early phase, passive activity for affected side and active activity for health side [were] suggested, such as combing the hair and hitting with health hands, raising the legs, clipping legs, contacting hands and feet" "During acute phase, turning over every 1-2 hours was practiced under supine position. Lateral recumbent position was avoided to prevent compression of limbs. During lateral position, pillow was used to support the affected side and the health upper limbs and raise

elbow. During the lateral position with the health side, elbow joint was stretched with palm toward health side, and the lower health limbs were extended backwardly. Exercise of limbs included the gentle pressing, massage, malaxtion from the distal end to proximal end twice a day, 20 min each time. Massage with safflower of regions surrounding should joint and from forearms to fingers was performed. Doctors should make patients believe their limbs were capable of moving for patients who were clear. The active movement dominated by the big nerves was suggested when patients showed signs of limbs activity, including raising hands, shoulder and leg and antielbow extension, hitting palms along the diagonal direction"

"During rehabilitation phase, patients were asked to sit by the bed with the health hands holding the bed, and legs dropping, and nurses standing by the affected side to prevent inclination toward the affected side. Once patients were capable of sitting stably by self, sitting exercise was initiated with body against bed, health hands holding bed, and nurses sitting by the side. Sitting exercises lasted from a few seconds to minutes, during which, patients were asked to swing affected limbs, 5 min each time and times and duration can be increased gradually. Walking exercise was initiated if patients were capable of sitting for 10-15 min without assistance. First patients were asked to do stepping on under the help of crutches. During exercise, center of gravity was gradually shifted to the affected side. Patients were asked to support the center of gravity under the nurses assistance,

then began the walking with health limbs till patients could take care of themselves" "Psychological rehabilitation, support, encourage, assiliation were given during the different psychological stage to make them exercise actively under good environment"

The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising functional task training, musculoskeletal intervention (active) and musculoskeletal intervention (passive)

Length of intervention period: unclear: "The average hospitalisation was (20 ± 9) days and (31 ± 11) days for rehabilitation group and control group respectively. Therapeutic effect of rehabilitation group was significantly superior to that of control group 15 days after treatment"

Number of sessions and length of individual sessions: dependent on patient condition (see above)

Intervention provider: nursing staff

(2) Control group (n = 87)

"received the general nursing"

The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising no intervention Length of intervention period: no intervention

Other outcome measures: 'Score of Neural Defection,' average length of hospitalisation

Number of sessions and length of individual sessions: no intervention

Intervention provider: no intervention This study is classified as intervention (functional task training, musculoskeletal (active)

, musculoskeletal (passive)) versus no treatment (Table 4)

Outcomes

Notes

Time points when outcomes were assessed: before and after treatment ... "15 days after treatment"
Abstract only

No data suitable for analysis This paper was written in English, and the extracts above are direct quotes

Risk of bias

Free of systematic differences in baseline characteristics of groups compared?	Low risk	"There was no significant difference in age, gender, course of disease, and score of neu- ral defection at admission"
Did authors adjust for baseline differences in their analyses?	Low risk	No information provided
Other bias	Unclear risk	No information provided

Li 2005

Methods	Study design: RCT Method of randomisation: "divided by draw method"
Participants	Number of participants: n = 61 Inclusion criteria: "Satisfied the 1995 Fourth National Conference on Cerebral Vascular Disease classification guidelines and 1982 International Meeting on Neurology assess- ment guidelines, first ever stroke, less than 70 years of age exclusive, one month within stroke onset inclusive and participant's informed consent" Exclusion criteria: "Previous stroke, does not include transient ischaemic attack, tran- sient ischaemic attack, with neurological deficits, conjunctival haemorrhage etc, severe complications and dementia"
Interventions	 (1) Motor relearning group (n = 31) "Motor relearning group strictly followed the Motor Relearning Program for rehabilitation. Consisting [of] seven components, each component was subdivided into the following 4 subsections for practice: (i) observation, analysis, comparison, and description of normal activity patterns and using the observation and comparison of occupational activity limitation to analyse the missing basic components and abnormal performance. (ii) Practising the missing exercise components, including practice explanation, instruction, language, visual feedback and manual guidance. (iii) ADL practice, including explanation, instruction, practice, language, visual feedback and manual guidance, re-as-

sessing, encouraging agility. (iv) Change in practice schedule, including scheduled and block practice, practice requiring self-supervision, creating a positive learning environment, involving the participation of family members and relevant personnel"

"Training method: (i) Upper limb function training: stimulate muscle activity and training control of reaching to objects -> maintaining muscle length, prevent contractures -> stimulate muscle control in the hand and training exercise control -> transferring from practice to ADL. (ii) Actinal surface function training: practise swallowing, facial exercise, improve breathing control -> transferring from practice to ADL. (iii) Lying to sitting on the edge of bed training -> transferring from practice to ADL. (iv) Sitting balance training: training postural adjustment during gravitational shifts -> increasing the complexity of training -> transferring from practice to ADL. (v) Sit to stand and stand to sit training. (vi) Standing balance training: bilateral lower limb loading training -> hip alignment practice -> initiation of quadriceps contraction practice -> training postural adjustment during gravitational shifts -> increasing difficulty -> transferring from practice to ADL. (vii) Gait training: standing training-> stepping practice -> ambulatory training -> increasing difficulty -> transferring from practice to ADL"

"Rehabilitation sequentially and progressively used the above seven components for intervention, adapting to the individual participant's treatment progress"

The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising functional task training and modality

Length of intervention period: not stated

Number of sessions and length of individual sessions: "45 min/session, 1/day, till the end of the study"

Intervention provider: not stated

(2) Neurodevelopmental therapy group (n = 30)

"Followed a combination of Bobath, proprioceptive neuromuscular facilitation (PNF) technique, Brunnstrom and Rood for rehabilitation"

"Neurodevelopmental therapy intervention: Using Bobath as the main component, intervention included 3 stages to treat: retardation stage, spasm stage and relative recovery stage: maintaining the correct supine position -> rolling practice -> sitting up from bed practice -> sitting balance training -> transfers training -> sit to stand training -> standing balance training -> gait training -> ADL training. The above followed the sequence and principles of neurodevelopment"

The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising functional task training, modality, musculoskeletal intervention (passive) and neurophysiological intervention Length of intervention period: not stated

Number of sessions and length of individual sessions: "45 min/session, 1/day, till the end of the study"

Intervention provider: not stated

This study is classified as active intervention one (functional task training) versus active intervention two (functional task training, musculoskeletal (passive), neurophysiological) (Table 6). Both intervention groups also received modality

Outcomes

Measures of Independence in ADL: Barthel Index Other secondary outcome measures: stroke lesion score evaluation form Time points when outcomes were assessed: day one of hospital admission and every month thereafter. For participants who were discharged before one month, assessment

Li 2005 (Continued)

	was done on discharge	
Notes	Original study translated from Chinese to English

Liao 2006		
Methods	Study design: RCT Method of randomisation: participants randomly divided into the two groups by the time of hospital admission	
Participants	Number of participants: n = 96 Inclusion criteria: "(1) Satisfied the 1995 Fourth National Conference on Cerebral Vas- cular Disease classification guidelines, confirmed by CT or MRI scan for the first ever stroke, (2) deficits in motor function, without any serious cognitive impairment, (3) aged between 40 to 80, no severe heart, liver, kidney or other organ diseases, (4) Glasgow Coma Scale > 8, medically stable within 1 week"	
Interventions	 (1) Treatment group (n = 48) "Both groups of patients were treated with conventional medicine to reduce oedema in brain, nourish brain and nervous system, improve blood circulation in brain, etc, treatment group besides conventional rehabilitation also received trunk control function training therapy" "Conventional rehabilitation method: (i) regular change in body positioning and main- 	

taining limbs in correct positions; (ii) Passive ranging exercises on affected limbs; (iii) Facilitative training of affected limbs; (iv) Bedside sitting-balance training: affected upper limb maintained in anti-spasticity position to prop against the bed and progressing from sitting with support to sitting without support, and by repeatedly training the patient to use head and trunk to shift towards the centre, sitting-balance was induced; (v) Sit to stand balance training: Patient clasped hands Bobath style, extended upper limbs, leaned head and trunk forward, placed both feet on ground, and extended torso, hip and knee to stand up, and in process of standing up, affected lower limb should fully bear weight; (vi) gait training: As patient's standing-balance and weight-bearing ability of affected lower limb increased, patient could undertake ambulatory training between parallel bars or assisted gait training, after which progressing to unaided gait training; (vii) ADLs training"

"Trunk control function training: (I) Training method while in lying position: (i). Therapist placed both hands on both sides of patient's hypochondrium, and in line with breathing motion, pushed down and centrally on thorax; (ii). Therapist placed palm on patient's abdomen, and in line with breathing motion, pushed up and inwards; (iii). With arms folded, independently extend the left and right shoulder forward, to train the twisting of upper trunk, and then with bent knees, keeping knees together, rotated pelvis to the right and left; (iv). Both legs or single-leg bridging exercise. (II) Training method while in sitting position: (i). Keeping both knees and hip bent and kept together, arms crossed to embrace knees, and moving forwards and backward; (ii). While sitting on edge of bed, patient supported knee with both hands, therapist used both hands to control patient's trunk to perform forward and backward pelvis motion, followed by extension and flexion of trunk on affected side via active assistive ranging exercise; (iii). While sitting on stool, with both hands propped on stool, trunk was twisted towards non-affected side and twisted towards affected side, followed by training in shifting of body weight towards non-affected side of the trunk; (iv). While sitting on side of bed, keeping knees and hip bent, both lower limbs lifted off the ground, to train trunk-balance. (III) Training method while in standing position: (i). Patient placed both hands on treatment table while in standing position, therapist used one hand to lightly push patients' buttocks, while other hand controlled trunk, to train torso extension; (ii). Therapist placed one hand on patient's buttocks, one hand on the abdomen, to train forwards and backwards motion of the pelvis; (iii). With both hands holding exercise bar, twisting and extension exercises were performed"

The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising functional task training and musculoskeletal intervention (passive) and neurophysiological intervention

Length of intervention period: 23.8 ± 6.7 days of treatment on average for this group Number of sessions and length of individual sessions: once a day, each time 45 minutes, every week six times

Intervention provider: not stated

(2) Control group (n = 48)

Control group received conventional rehabilitation as described above

The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising functional task training and musculoskeletal intervention (passive)

Length of intervention period: 24.6 ± 6.5 days of treatment on average for this group Number of sessions and length of individual sessions: once a day, each time 45 minutes,

Liao 2006 (Continued)

	every week six times Intervention provider: not stated This study is classified as active intervention one (functional task training, musculoskele- tal (passive), neurophysiological) versus active intervention two (functional task training, musculoskeletal (passive)) (Table 6)
Outcomes	Measures of motor function: Fugl-Meyer (balance ability and motor function of lower extremity) Other secondary outcome measures: Sheikh (truncal control) Time points when outcomes were assessed: before and after intervention
Notes	Original study translated from Chinese to English Note: Treatment group has been classified as neurophysiological based on the description of handling techniques provided in the paper. No reference is made to Bobath or Davies. The categorisation will be explored in a sensitivity analysis

Lincoln 2003

Methods

Study design: RCT

Method of randomisation: blocked randomisation. Computer-generated random sequence of numbers in opaque sealed envelopes opened sequentially by researcher

Participants	Number of participants: n = 120 Inclusion criteria: stroke less than two weeks previously Exclusion criteria: excluded if unconscious on admission, unable to toilet self before stroke, unable to tolerate more than 30 minutes of physical tasks and living farther than 25 km from hospital or if no informed consent given
Interventions	 (1) Neurophysiological (Bobath) (n = 60) "Treatment delivered by different groups of physiotherapists using prepared written guidelines, consisting of theoretical concepts for practice and main clinical objectives, based on their own knowledge and experience and their interpretation of the literature" Techniques were not described. Bobath-based treatment was delivered by the unit's existing physiotherapists, who had used this approach routinely before the start of the study Prepared written guidelines were available The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising neurophysiological intervention Length of intervention period: "treatment continued for as long as was needed"approach continued as outpatient if necessary Amount matched to "typical amount" given by existing ward physiotherapists Number of sessions and length of individual sessions: median of 23 minutes per weekday Intervention provider: more time was spent with physiotherapist and physiotherapy assistant together for this treatment group. Stated that occupational therapists also used this approach (2) Motor learning (n = 60) "Treatment delivered by different groups of physiotherapists using prepared written guidelines, consisting of theoretical concepts for practice and main clinical objectives, based on their own knowledge and experience and their interpretation of the literature" Techniques were not described. Motor-learning treatment was delivered by two physiotherapists, who previously had 'insufficient experience of treatment' but who were given training Prepared written guidelines were available The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising functional task training Length of intervention period: "treatment continued for as long as was needed"approach continued as outp
Outcomes	Measures of Independence in ADL: Barthel Index; EADL Measures of functional independence: Motor Assessment Scale; Rivermead Motor Assessment Measures of voluntary movement: 10-Metre Walk test Measures of tone/spasticity: Modified Ashworth Scale Other measures: Nine-Hole Peg test; Nottingham Sensory Assessment; length of stay Time points when outcomes were assessed: "Measures were performed by a blinded

Lincoln 2003 (Continued)

assessor at baseline, and then at 1, 3, and 6 months after baseline"

Notes

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Computer-generated random sequence of numbers in opaque sealed envelopes opened sequentially by researcher ("Allocation to treatment groups was by a computer generated random sequence pro- vided by a therapist not involved with the trial, with notification delivered in opaque sealed envelopes. Blocked randomisation was used to ensure approximately equa numbers of patients in each group at any time. Patients were screened consecutively on admission to the ward and those that met the inclusion criteria were referred for initial assessment. After the initial assess- ment was completed, a research therapists opened the next envelope and informed the therapists providing the treatments of the group allocation")
Allocation concealment (selection bias)	Low risk	Allocation to treatment groups was by a computer-generated random sequence provided by a therapist not involved with the trial
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Participant not blinded ("Patients were asked not to mention their treatment or therapist to the assessor") Therapist not blinded Assessor was blinded (Outcome assess- ments were completed at one, three and six months after random allocation by an assessor who was blind to the group allo- cation) ("To ensure masking, assessments of inpatients occurred in a room separate from the ward and patients were brought to the assessor there whenever possible. For later examination of the success of masking, the assessor recorded a guess of the patient's group allocation at each assessment")

Lincoln 2003 (Continued)

Incomplete outcome data (attrition bias) All outcomes	Low risk	Dropouts were accounted for 52/60 in Bobath group and 47/60 in motor learning group remained at one month; 43/ 60 and 42/60 completed assessments, re- spectively, at three months; and 45/60 and 42/60, respectively, at six months
Free of systematic differences in baseline characteristics of groups compared?	Low risk	"The groups were not significantly differ- ent in age, gender, side of stroke, type of lesion, or cognitive impairments"
Did authors adjust for baseline differences in their analyses?	Low risk	No information provided
Other bias	Unclear risk	Some possibility of contamination between groups, as physiotherapists providing the motor learning intervention were previ- ously using Bobath therapy and therefore may have reverted to using some Bobath techniques Also some possibility of contamination due to participants being inpatients on the same unit: the study authors state: "some as- pects of the treatments could not be imple- mented because both treatments were oc- curring on the same rehabilitation wards and there was a risk of treatment contami- nation" Both groups had received treatment based on the Bobath approach before randomisa- tion The Bobath treatment was provided by physiotherapists who had previously used it, while the motor learning treatment was provided by physiotherapists previously in- experienced in motor learning who were given training before the interventions

Liu 2003

Methods	Study design: RCT Method of randomisation: not stated
Participants	Number of participants: n = 120 Inclusion criteria: "There were 120 hemiplegic patients with cerebral apoplexy from July 2000 to February 2001 (not counting those with serious heart, lung, kidney, and stomach complication and disturbance of consciousness). We made a diagnosis according to WHO standards after using CT or MRI head diagnosing without exception"

Interventions	 (1) Rehabilitation group (n = 60) "All the 120 patients were treated according to endoneurological routine. On this basis we made recovery training for the rehabilitation group using modern technology. In accordance with patients condition, we took appropriate recovery measures (PT, OT), such as favourable limb position in bed, particular passive movement, healthy limb active movement and sick limb movement with the help of the healthy, sitting position balancing training, dressing and eating, speaking and ADL training" "The rehabilitation group started to accept the treatment in 3-5 days after attack when the patients had been conscious, vital signs had been smooth, nervous signs had not advanced within 48 hours" The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising functional task training, musculoskeletal intervention (active) and musculoskeletal intervention (passive) Length of intervention period: 15 days Number of sessions and length of individual sessions: "four times a day, 30 minutes at every turn" Intervention The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising no intervention (passive) Length of intervention period: 15 days Number of sessions and length of individual sessions: "four times a day, 30 minutes at every turn" Intervention The individual components delivered are listed in Table 3. Outcomes	Measures of functional independence: MAS (item five)
	Measures of balance and postural control: Functional Reach Test
	Time points when outcomes were assessed: "were measured prior to, immediately after,
	and two months after intervention"

Notes

Risk	of	bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	"To ensure allocation was concealed, ran- domisation was by numbered, sealed, opaque envelopes"
Allocation concealment (selection bias)	Low risk	No information provided
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Participant was blinded to study aims ("To increase the likelihood that subjects were blind to group allocation, neither the exact purpose of the research nor the types of exercises that subjects would be receiving were specified and both mobility and upper limb function [were] measured") Therapist not blinded Assessor was blinded ("Outcome measures were collected at Weeks 0, 6, and 14 by a measurer blinded to group allocation")
Incomplete outcome data (attrition bias) All outcomes	Low risk	Dropouts accounted for 23/26 completed intervention 21/26 assessed at six weeks
Free of systematic differences in baseline characteristics of groups compared?	Low risk	Characteristics of the experimental group and the control group are similar
Did authors adjust for baseline differences in their analyses?	Low risk	No information provided
Other bias	Unclear risk	Compliance with the home exercise regime is a potential confounding variable This was measured and, on average, partic- ipants recorded that they practised 75% of the times that they were instructed to do so

Methods	Study design: single-blind RCT Method of randomisation: "prospective, randomized, single-blind, attention controlled clinical trial of circuit-based rehabilitation in adults at least 6 months after stroke" 'Participants were randomly assigned to the exercise or control group through the use of computer-generated random numbers by an individual not associated with the study. Randomization was revealed to each participant by the principal investigator after the second baseline assessment"
Participants	Number of participants: n = 58 Inclusion criteria: "1 or more strokes more than 6 months earlier, discharged from rehabilitation, and were able to walk independently (with an aid if necessary). Some residual gait difficulty was required, as defined by a score of less than 2 on at least 1 of the walking items of the physical functioning scale of the 36-Item Short Form Health Survey" Exclusion criteria: "Progressive neurologic disease, other significant health problems that adversely affected walking ability, more than 2 falls in the previous 6 months and unstable cardiac conditions, uncontrolled hypertension, or congestive heart failure"
Interventions	 (1) Exercise group (n = 31) "There were 15 stations in the circuit, which were graded to each participant's ability and progressed as tolerated. Each station contained either a task-oriented gait or standing balance activity, or strengthening of a lower extremity muscle in a way designed to improve gait. Details of the content of each station and examples of progressions are provided in an Appendix. The total exercise time was 30 minutes, although sessions lasted between 50 to 60 minutes, including stretching. Participants spent 2 minutes at each station of the circuit, with time allowed to move between stations and receive instructions for the next station. Details about exercise intensity and/or repetitions performed at each station were recorded for each participant." The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising functional task training and musculoskeletal intervention (active) Length of intervention period: four weeks Number of sessions and length of individual sessions: in 12 group circuit exercise sessions three times a week Intervention provider: "groups contained up to 9 participants and were led by 1 of the investigators (S.M.) assisted by 2 physiotherapy students" (2) Control group (n = 27) "The control group was run by an occupational therapist and consisted of 4 social and 4 educational sessions. Detailed content of the sessions is available in Appendix. The duration of the control for possible effects of dosage" "Matching for duration and not number of sessions was a pragmatic choice based on resources, allowing 1 intervention session a weekday to be scheduled over the 4-week intervention period." The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as attention control (social) Length of intervention is categorised as attention con

Mudge 2009 (Continued)

	Intervention provider: occupational therapist This study is classified as intervention (functional task training, musculoskeletal (active)) versus attention control (Table 5)
Outcomes	Measures of motor function: Rivermead Mobility Index Measures of voluntary movement: Six-Minute Walk test, Timed 10-Metre Walk test Other secondary outcome measures: Physical Activity and Disability Scale (PADS), Activities-Specific Balance and Confidence Scale, mean number of steps/d (measured by the StepWatch Activity Monitor) Time points when outcomes were assessed: "Two baseline testing sessions 3 weeks apart were performed to ensure that participant measures were stable. The testing sessions were repeated immediately after the group sessions (postintervention) and at 3 months (follow-up). All tests were performed once, and all testing sessions were identical"
Notes	Data provided are means and ranges. For analysis, standard deviations have been esti- mated by calculating (upper range - lower range)/four

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	"randomly assigned to the exercise or con- trol group through the use of computer- generated random numbers by an individ- ual not associated with the study"
Allocation concealment (selection bias)	Low risk	"Participants were not blind because they were aware of their own group allocation, which was revealed after the second testing session. Participants were instructed not to discuss group allocation with the assessor. The testing sessions were carried out in the same rehabilitation clinic as the interven- tion groups but were scheduled at different times to maintain blinding of the assessor"
Blinding of outcome assessment (detection bias) All outcomes	Low risk	"Outcome assessment was performed by an independent physiotherapist blind to treat- ment assignment"
Incomplete outcome data (attrition bias) All outcomes	Low risk	Dropouts accounted for
Free of systematic differences in baseline characteristics of groups compared?	Low risk	"There was no significant difference be- tween the baseline characteristics of the 2 groups"
Did authors adjust for baseline differences in their analyses?	Low risk	No information provided

Mudge 2009 (Continued)

Mudie 2002 (Continued)

	The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising usual care (not stated) Length of intervention period: six weeks Number of sessions and length of individual sessions: received 'standard' treatment Intervention provider: physiotherapists and occupational therapists This study is classified as active intervention one (functional task training) versus active intervention two (neurophysiological) (Table 6) versus usual care (not stated) (Table 5)
Outcomes	Measures of independence in ADL: Barthel Index Measures of postural control and balance: symmetry in sitting, weight distribution in sitting Time points when outcomes were assessed: "Measurements were performed using the BPM daily before treatment sessions, two weeks after cessation of treatment and 12 weeks post study"
Notes	Intervention for group (one) based on components from motor learning theory, but as this intervention is feedback only (and trials of feedback only have been excluded from this review), the data from this group will not be used

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Random number tables; random num- bers assigned alternately to group; random number drawn by independent person and participant assigned to appropriate group ("Forty numbers from a random numbers table were sequentially drawn from a box by a clinician independent of the study. The numbers were written alternately in columns headed with the training regimes of the four groups until all 40 numbers were placed. The slips of paper containing the random numbers were replaced in an opaque canister that was kept in a locked filing cabinet in the senior investigator's of- fice")
Allocation concealment (selection bias)	Low risk	"On admission of a patient to the study, an independent person drew a number from the container and the patient was allocated to the treatment group with the matching number"
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Unclear whether participant was blind Therapist not blinded, although blinded to data ("The therapists administering the training had no access to weight distribu-

Mudie 2002 (Continued)

		tion data of subjects before or during train- ing. Monitoring by the senior investigator ensured that the research assistants measur- ing and recording the data remained blind to the patients' training regime and that therapists remained blind to the measure- ment data") Assessor was blinded ("Testing and record- ing of results [were] conducted by grant- funded research assistants (occupational therapy students and assistants) who were independent of the rehabilitation wards from which the subjects came and unaware of the treatment subjects were to receive") "Group allocation was more difficult to hide from the assistants (successful in ap- proximately 75% of cases) but blinding of therapists to measurement data was suc- cessful in every case"
Incomplete outcome data (attrition bias) All outcomes	Low risk	Dropouts accounted for 33/40 completed intervention
Free of systematic differences in baseline characteristics of groups compared?	Low risk	"no significant difference in ages between the four stroke groups"
Did authors adjust for baseline differences in their analyses?	Low risk	No information provided
Other bias	Unclear risk	Therapists providing 'standard' therapy, given in addition to study intervention, could have contaminated groups with the treatment they provided It is stated that "co-operation of both occupational therapists and physiothera- pists was sought to ensure that the control group received no specific weight-distribu- tion training during the study period to the first follow up" The 'standard' treatment provided after the end of the intervention period was not monitored and could have involved sub- stantial Bobath weight-distribution train- ing Unskilled research assistants (occupational therapy students and assistants) collected outcome data, which may have resulted in errors

It is unclear whether the Barthel Index was collected by researchers or obtained from participant records

Pang 2003		
Methods	Study design: RCT Method of randomisation: not stated "All the patients were randomly divided into rehabilitation group and control group"	
Participants	Number of participants: n = 86 Inclusion criteria: "diagnosed according to diagnostic criteria established in the Fourth National Cerebral Vascular Disease Conference in 1995"	
Interventions	 (1) Rehabilitation group (n = 50) "Both groups received routine treatment in department of internal neurology. Cerebral edema [was] controlled by 20% mannitol and support treatment. In rehabilitation group, superearly stage, flaccid paralysis and recovery stage rehabilitation care were performed based on routine internal medicine treatment" "(i) Superearly stage care: Carefully observe and keep stable life signs and improve basical care within the first 3 days. Keep functional position, including flexion and abduct of shoulder joint, extension of the elbow, dorsal extension of wrist, extension or light flexion of fingers, flexion of knee and hip joint and keep ankle joint in medium position. Turn the body over in regular time and change position, healthy side lateral recumbent position and injured side lateral recumbent position. Still, the patients were required to take injured side lateral recumbent position as much as possible to simulate feeling of the injury side and is advantageble to motion of the healthy side of the body" "(ii) Flaccid paralysis stage care: After 3 weeks' basic treatment, proximal to distal massaging can be taken based on stable life signs and maintaining functional position. After that, proper short time passive flexion and extension were practiced within the limit of the various articular motion. Motion sequence is started from the bigger joint to the smaller one and stick to from little to large range, proper and step by step principle. Violence was avoided to prevent soft tissue injured. Motion is according to the fatigue status of the patients, with 2 or 3 times a day and 30 min each time" "(iii) Early rehabilitation care: It is important to perform ADL exercise 3 to 4 weeks after 	

	injury. The patients were required to practice initiative and passive motion, including position transversion, balance and functional exercise of upper extremities and hand, overload exercise of the lower extremities and flexion and extension of the hip, knee and ankle joint and language exercise, with 1 time per day and 30 to 60 min each time" The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising functional task training and musculoskeletal intervention (passive) Length of intervention period: four weeks Number of sessions and length of individual sessions: dependent on phase of recovery Intervention provider: not stated (2) Control group (n = 36) "Patients in the control group were taken routine care during the experiment" The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising no intervention Length of intervention period: no intervention Number of sessions and length of individual sessions: no intervention Length of intervention period: no intervention This study is classified as intervention (functional task training, musculoskeletal (passive)) versus no treatment (Table 4)

Notes	Original study translated from Chinese to English Note: Treatment group received both notoginseng saponin treatment and hyperbaric oxygen treatment as well as the physiotherapy components

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	"according to the enrolled sequence with 3 cases in 1 group". No further details provided
Allocation concealment (selection bias)	High risk	Implementation of study design was done by first study author
Blinding of outcome assessment (detection bias) All outcomes	High risk	Outcome assessment was done by fourth and fifth study authors
Incomplete outcome data (attrition bias) All outcomes	Low risk	Dropout accounted for Two participants withdrew from control group
Free of systematic differences in baseline characteristics of groups compared?	Unclear risk	No information provided
Did authors adjust for baseline differences in their analyses?	Unclear risk	No information provided
Other bias	High risk	Treatment group received both notogin- seng saponin treatment and hyperbaric oxygen treatment as well as the physiother- apy components

Pollock 1998

Methods	Study design: RCT Method of randomisation: blocked randomisation, with two control (neurophysiology) : one intervention (mixed); sealed opaque envelopes numbered and opened sequentially
Participants	Number of participants: n = 28 Inclusion criteria: diagnosis of stroke less than six weeks previously, attending regular physiotherapy sessions, able to achieve one minute of independent sitting balance, unable

Pollock 1998 (Continued)

	to achieve 10 independent steps, no known disabilities, pathology or neurological deficit that affected mobility before the current hospital admission and able to understand the nature of the study and give informed consent
Interventions	 (1) Additional motor learning (n = 9) Independent practice of context-specific tasks Supervised practice of seated reaching tasks The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising functional task training Length of intervention period: four weeks Number of sessions and length of individual sessions: addition of one hour per day, five days per week, in addition to usual care Intervention provider: physiotherapists (2) Usual care (Bobath) (n = 19) Based on assessment by treating physiotherapist: routine care The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as usual care (neurophysiological intervention) Length of intervention period: four weeks Number of sessions and length of individual sessions: usual care, normally once per day, five days per week Intervention provider: physiotherapists This study is classified as intervention (functional task training) versus usual care (neurophysiological) (Table 5)
Outcomes	Measures of independence in ADL: Barthel Index Measures of postural control and balance: symmetry during sitting, standing, rising to stand, sitting down; weight transference during reaching Time points when outcomes were assessed: at end of intervention (six weeks)
Notes	Participants who were discharged from hospital before the end of the study period (six weeks) were not followed up, resulting in considerable numbers of dropouts from the study

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Blocked randomisation, with two con- trol (neurophysiology): one intervention (mixed); sealed opaque envelopes num- bered and opened sequentially
Allocation concealment (selection bias)	Low risk	No information provided
Blinding of outcome assessment (detection bias) All outcomes	High risk	Participant not blinded Therapist not blinded Assessor not blinded

Pollock 1998 (Continued)

Incomplete outcome data (attrition bias) All outcomes	High risk	Dropouts accounted for 11/19 in the control group and five of nine in the intervention group completed final assessment "This pilot study had low numbers of par- ticipants, and a relatively high number of withdrawals"
Free of systematic differences in baseline characteristics of groups compared?	Unclear risk	Difference in gender distribution between the groups, but other characteristics similar
Did authors adjust for baseline differences in their analyses?	Unclear risk	No information provided
Other bias	High risk	The control group received no additional treatment, and the treatment group re- ceived the intervention away from the ward and from control group participants; there- fore it is unlikely that there was any con- tamination between groups Attendance at the practice sessions was vol- untary and varied considerably between participants The culture of the ward and rehabilitation was identified to be based on Bobath prin- ciples, and practice was found to conflict with these; this may have affected the moti- vation of participants in the practice group

Qian 2004

Methods	Study design: RCT Method of randomisation: "by participants drawing lots"
Participants	Number of participants: n = 42 Inclusion criteria: not stated
Interventions	(1) Treatment group (n = 23) "Participants in the treatment group received therapy from a mix of approaches: (i) Exercises focused on the affected limbs with appropriate progression, 20 min/session, 1/day. (ii) Neuromuscular facilitation techniques, including Rood, PNF, Brunnstrom, Bobath and functional stimulative techniques, 20 min/session, 1x/day. (iii) Electrical stimulation: using Auto Move AM800, current set at between 0-60mA into 2.5k Ω ; set at 100-400 µs; frequency 10-100Hz; continuous stimulation time at between 2- 20s; resting time between stimulation 2-50s. Intensity is set to as tolerated by participants, with each treatment lasting 20 min/session, 1/day. (iv) ADL practice: 1/day. (v) Rehabilitation included limb positioning, regular change in body position in bed etc. (vi) Acupuncture, 1/day"

	The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising functional task training, modality, musculoskeletal intervention (passive) and neurophysiological intervention Length of intervention period: not stated Number of sessions and length of individual sessions: session length dependent on technique applied (see above) Intervention provider: "Exercises were assisted by a nurse or family under supervision by a therapist" (2) Control group (n = 19) "The control group received routine rehabilitative instruction only" The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising no intervention Length of intervention period: no intervention Number of sessions and length of individual sessions: no intervention Intervention provider: no intervention This study is classified as intervention (functional task training, musculoskeletal (passive) , neurophysiological) versus no treatment (Table 4). The intervention group also received modality
Outcomes	Other secondary outcome measures: Functional Comprehensive Assessment (FCA) Time points when outcomes were assessed: before and one, three and six months after intervention
Notes	Original study translated from Chinese to English No data suitable for analysis

(iv) ADL training, stimulation, using Beijing-pro- with specifications: mid-frequent 1/5 - 150 Hz; tune shape of peak output current: 50 mA < continuous, pause, rest, change voltage: main electricity 220V, two ends of muscle to be stim tolerance, with treatment time once a day" "In addition flexor reflexes were the therapist used a hand or h affected side's sole on the plant and on lower extremities of pa dorsiflexion would be induced active participation by patient; practice for 20 min, once a day The individual components d components, this intervention modality, neurophysiological in Length of intervention period: Number of sessions and length nique applied (see above) Intervention provider: therapis (2) Control group (n = 20) "Received regular rehabilitation The individual components d components, this intervention	Exclusion criteria: "Severe premorbid illness, cognitive impairment and severe complications" (1) Therapy group (n = 20) "Regular rehabilitation therapy: (i) therapeutic exercise for hemiplegia, with therapeutic exercises corresponding to different stages, 20 min each time, once a day. (ii) neuro- muscular stimulative technique, including Rood technique, PNF technique, Bobath technique etc, 20 min each time, once a day. (iii) gait training, 20 min each time, once a day. (iv) ADL training, 20 min each time, once a day. (v) functional electrical stimulation, using Beijing-produced J18A1 model computerised pulse therapy device, with specifications: mid-frequency pulse frequency 4 kHz, low-frequency pulse frequency 1/5 - 150 Hz; tune shape of wave to square wave, exponential wave, triangle wave; peak output current: 50 mA < Current < 100 mA (resistance 500 α); tuning method: continuous, pause, rest, change settings; strength control: continuous control; working voltage: main electricity 220V, power ≤ 15 W. Two working electrodes were placed on two ends of muscle to be stimulated, at the tendons, strength set at patient's limit of tolerance, with treatment time being 20 min each time, once a day. (vi) acupuncture, once a day" "In addition flexor reflexes were used to provide therapy for the lower limbs, as described: the therapist used a hand or hard object, without damaging the skin, to stimulate the affected side's sole on the plantar side, such that the patient felt a tolerable discomfort, and on lower extremities of patient's affected side, hip flexion, knee flexion and ankle dorsiflexion would be induced; force would increase from light to heavy, with focus on active participation by patient; each time lasting 10s, 30s between each practice; repeated practice for 20 min, once a day" The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising functional task training, modality, neurophysiological inter	

Qian 2005 (Continued)

	Length of intervention period: not stated Number of sessions and length of individual sessions: session length dependent on tech- nique applied (see above) Intervention provider: therapist This study is classified as intervention (functional task training, neurophysiological) ver- sus usual care (functional task training, neurophysiological) (Table 5). Both intervention groups also received modality
Outcomes	Measures of motor function: Fugl-Meyer Assessment (lower limb) Time points when outcomes were assessed: before and one month after intervention
Notes	Original study translated from Chinese to English

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Randomisation done by participants draw- ing lots. No further details provided
Allocation concealment (selection bias)	High risk	Implementation of study design was done by first study author
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Outcome assessment was blinded
Incomplete outcome data (attrition bias) All outcomes	Unclear risk	No dropouts described
Free of systematic differences in baseline characteristics of groups compared?	Low risk	No significant baseline differences
Did authors adjust for baseline differences in their analyses?	Low risk	No information provided
Other bias	Unclear risk	No information provided

Richards 1993

Methods	Study design: RCT Method of randomisation: sealed envelopes, opened remotely by telephone request Blocked randomisation, stratified according to prognostic category, with randomly vary- ing block size
Participants	Number of participants: n = 27 Inclusion criteria: middle cerebral artery infarct, confirmed by CT scan, living less than 50 km from Quebec, between 40 and 80 years old, zero to seven days since onset of

Richards 1993 (Continued)

	stroke, no other neurological problems, no major medical problems that would interfere with rehabilitation, not independent in ambulation and not unconscious at onset
Interventions	 (1) Early-mixed (n = 10) Intensive and focused "Goal was to promote gait relearning through locomotor activities that were adapted to the individual level of motor recovery" Techniques included tilt table; limb load monitor, resistive exercises, with isokinetic exercises; treadmill training The individual components delivered are listed in Table 3. Based on the individual com- ponents, this intervention is categorised as comprising functional task training, modality, musculoskeletal intervention (active) and musculoskeletal intervention (passive) Length of intervention period: whilst inpatient Number of sessions and length of individual sessions: 'intensive' Intervention provider: physiotherapists (2) Early-neurophysiological (Bobath) (n = 8) Techniques not described but communication with the study author confirms this in- tervention as 'neurodevelopmental or Bobath' The individual components delivered are listed in Table 3. Based on the individual com- ponents, this intervention is categorised as comprising neurophysiological intervention Length of intervention period: whilst inpatient Number of sessions and length of individual sessions: 'intensive' Intervention provider: physiotherapists (3) Conventional-neurophysiological (Bobath) (n = 9) The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising usual care (neurophysiological intervention) Length of intervention period: whilst inpatient Number of sessions and length of individual sessions: as usual care (less than treatment groups) Intervention provider: physiotherapists This study is classified as active Intervention one (functional task training, musculoskele- tal (active), musculoskeletal (passive)) versus active intervention two (neurophysiologi- cal) (Table 6) versus usual care (neurophysiological) (Table 5).
Outcomes	Measures of independence in ADL: Barthel Index Measures of functional independence: Fugl-Meyer Motor Assessment Measures of postural control and balance: Berg Balance Scale Measures of voluntary movement: temporal gait parameters Other secondary outcome measures: Canadian Stroke Scale Time points when outcomes were assessed: "Gait movements and muscle activations were evaluated in the Motor Evaluation Laboratory six weeks, three months, and six months after stroke"
Notes	Analysis based on comparison of neurophysiological (early) with mixed (early), as these two groups are comparable in terms of timing and intensity

Risk of bias

Richards 1993 (Continued)

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Sealed envelopes, opened remotely by tele- phone request
Allocation concealment (selection bias)	Low risk	No information provided
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Unclear whether participant was blinded Therapist not blinded Assessor was blinded
Incomplete outcome data (attrition bias) All outcomes	Unclear risk	23/27 completed intervention Dropouts not accounted for Participants with missing data were dropped from analysis
Free of systematic differences in baseline characteristics of groups compared?	Unclear risk	No information provided
Did authors adjust for baseline differences in their analyses?	Unclear risk	No information provided
Other bias	Unclear risk	The same two therapists provided treat- ment to both treatment groups, creating the possibility of contamination between groups

Salbach 2004

Methods	Study design: RCT Method of randomisation: stratified blocked randomisation, stratified according to three levels of walking deficit Computer-generated numbers in sealed opaque envelopes, managed by person not in- volved in the study
Participants	Number of participants: n= 91 Inclusion criteria: clinical diagnosis of stroke, less than one year post stroke, residual walking deficit but able to walk 10 m (with or without aid or supervision), discharged from physical rehabilitation and living in community
Interventions	 (1) Motor learning (mobility) (n = 44) Task-orientated training of walking "Standardised programme, supervised by a physical or occupational therapist, of 10 walking-related tasks designed to strengthen the lower extremities and enhance walking balance, speed and distance in a progressive manner" The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising cardiopulmonary intervention,

	functional task training and musculoskeletal intervention (active) Length of intervention period: six weeks
	Number of sessions and length of individual sessions: 18 sessions given three times per week. Recommended that participants carry over walking component of the programme to home
	Intervention provider: physical or occupational therapist (2) Placebo control (motor learning, upper limb) (n = 47) Functional upper extremity tasks, done in sitting The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising upper limb training Length of intervention period: six weeks Number of sessions and length of individual sessions: 18 sessions given three times per week. Recommended that participants carry over walking component of the programme to home Intervention provider: physical or occupational therapist This study is classified as intervention (functional task training, musculoskeletal (active)) versus attention control (upper limb) (Table 5). The intervention group also received cardiopulmonary intervention
Outcomes	Measures of postural control and balance: Berg Balance Scale Measures of voluntary movement: gait speed Time points when outcomes were assessed: "evaluations were conducted by trained evaluators at baseline, and on completion of the intervention (mean four days)"
Notes	Intervention two comprised upper limb training. Although upper limb training might be classed as a subcomponent of functional task training, for the purposes of comparisons in this review, we have categorised this intervention as an attention control. This is because the upper limb training was delivered alone (i.e. no other subcomponents of functional task training were delivered), and therefore no active treatment was aimed at lower limb or balance outcomes

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Computer-generated numbers in sealed opaque envelopes, managed by person not involved in the study
Allocation concealment (selection bias)	Low risk	No information provided
Blinding of outcome assessment (detection bias) All outcomes	High risk	Participant not blinded Therapist not blinded Assessor was blinded However, unblinding of the outcome eval- uators occurred for 18 of 42 mobility and 16 of 43 upper extremity evaluations

Salbach 2004 (Continued)

Incomplete outcome data (attrition bias) All outcomes	Unclear risk	Dropouts accounted for 84/91 completed intervention
Free of systematic differences in baseline characteristics of groups compared?	Unclear risk	No information provided
Did authors adjust for baseline differences in their analyses?	Unclear risk	No information provided
Other bias	Unclear risk	No information provided
Shin 2011		
Methods	Study design: RCT Method of randomisation: "subjects were ra	undomly allocated to one of into two groups"
Participants	Number of participants: n = 21 Inclusion criteria: "Subjects who were between 6 months and 5 years since diagnosis of stroke, subjects with hemiplegia of the lower extremities" Exclusion criteria: "subjects who could not ride a bicycle or perform functional exercise due to arthritis, low-back pain, or degenerative joint disease; subjects who were receiving medical treatment due to other symptoms; and subjects who could not follow the in- structions due to low perceptive abilities, cognitive disorder, or communication disorder"	
Interventions		

The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising cardiopulmonary intervention, functional task training and musculoskeletal intervention (active)

Length of intervention period: four weeks

Number of sessions and length of individual sessions: 60 minutes per day, five times a week

Intervention provider: physical therapist ("aerobic exercise was conducted with the assistance of a caregiver or family member under the supervision of a physical therapist") (2) Conventional exercise group (n = 10)

"Special instructions were not given to the physical therapist in charge, and the conventional training was done as usual. The therapist focused on re-educating normal movement during functional activities that were meaningful to the patients. Training was composed of balance exercise, posture control exercise, and gait exercise. Keeping normal movement of the pelvis for balance and posture control was emphasized. The therapist judged that working on increasing anterior and posterior pelvic tilt would improve weight transfer and hip extension during gait, leading to improvements in selective distal control of the knee and the foot. Trunk control and alignment can affect muscle tone, range of motion, and control of the limb. For the upper limbs, treatment was conducted focusing on movement of the scapular. For balance exercise, weight transfer exercise and reaching exercise were alternately performed on the affected side and the unaffected side in the sitting or standing position. Bridging exercise was performed to strengthen the trunk muscles. Selective movement of each joint of the shoulder, elbow, knee and ankle joint was performed to facilitate upper and lower limb movement. For gait exercise, training in weight transfer during gait was conducted by planting the unaffected side foot at the front and back of the body. Gait training was divided between the stance phase and the swing phase, and exercises for each phase were performed. In addition, stair climbing practice and gait training for crossing obstacles were conducted. Patients did not do the same exercise every training day but suitable exercises were selected according to the goals of each patient and the therapist. The intensity of each exercise was decided by the therapist considering each patient's capacity for exercise"

The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising functional task training, musculoskeletal intervention (active) and neurophysiological intervention

Length of intervention period: four weeks

Number of sessions and length of individual sessions: 60 minutes per day, five times a week

Intervention provider: physical therapist

This study is classified as active intervention one (functional task training, musculoskeletal (active)) versus active intervention two (functional task training, musculoskeletal (active), neurophysiological) (Table 6). Active intervention group one also received cardiopulmonary intervention

Outcomes	Measures of postural control and balance: Berg Balance Scale (dynamic balance), force platform (static balance) Time points when outcomes were assessed: "start of the interventionand after comple- tion of the 4-week intervention"
Notes	Note: The conventional exercise group was categorised as comprising 'neurophysiolog- ical' components, as a description of facilitation of 'normal movement' was provided. However, this was referenced to Bobath/Davies

Risk of bias

Thaut 2007		
Methods	Study design: RCT Method of randomisation: "2 research centers in Germany and the United States were selected by a random number table. Patients were randomly assigned to either the ex- perimental (RAS; n = 43; male = 22, female = 21) or control (neurodevelopmental tech- nique/Bobath; n = 35; male = 19, female = 16) training group (see Table 1). Treatment allocation was accomplished by computerized random number generators in both cen- ters"	
Participants	Number of participants: n = 78 Inclusion criteria: not stated ("from an eligible catchment pool of 155 patients") "Patients entered the study within 4 weeks of onset, as soon as they could complete 5 stride cycles with handheld assistance by the therapist, that is, with no more than support of the forearm, wrist, and elbow at approximately 90 degrees of elbow flexion on the nonparetic side. Handheld assistance was available to all patients throughout training when needed"	
Interventions	 (1) Rhythmic auditory stimulation (n = 43) "RAS training followed established protocols using a metronome and specifically prepared music tapes in digital MIDI format to ensure temporal precision and tempo stability as well as full capacity for frequency modulation of the stimulus based on patient needs. After an initial cadence assessment, cuing frequencies were matched to the gait cadence for the first quarter of the session. During the second quarter, cue frequencies were increased in 5% increments as kinematically indicated without compromising postural and dynamic stability. During the third quarter, adaptive gait patterns, for example, ramp or step walking, were practiced. The last quarter was spent fading the cues intermittently to train for independent carryover" The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising functional task training Length of intervention period: three weeks Number of sessions and length of individual sessions: "gait training daily for 30 minutes, 5 times per week" Intervention provider: "Four gait therapists for each group conducted the training to ensure consistency in training protocols and procedures. Each center had its own independently trained pool of therapists" (2) Neurodevelopmental therapy (NDT)/Bobath-based training (n = 35) "control group trained the same amount of time and distance, following NDT and Bobath principles as well as using similar instructions about gait parameters to practice, but without rhythmic auditory cuing" 	

Thaut 2007 (Continued)

	The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising functional task training and neurophysiological intervention Length of intervention period: three weeks Number of sessions and length of individual sessions: "gait training daily for 30 minutes, 5 times per week" Intervention provider: "Four gait therapists for each group conducted the training to ensure consistency in training protocols and procedures. Each center had its own inde- pendently trained pool of therapists" This study is classified as active intervention one (functional task training) versus active intervention two (functional task training, neurophysiological) (Table 6)
Outcomes	Measures of independence in ADL: Barthel Index Measures of motor function: Fugl-Meyer Assessment Measures of voluntary movement: gait velocity, stride length, cadence and symmetry Time points when outcomes were assessed: "All patients were tested 1 day before the training sessions started and 1 day after the last training session"
Notes	"All available participant data after removing dropout participants were analyzed in an intention-to-treat analysis"

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	"selected by a random number table"
Allocation concealment (selection bias)	Low risk	"Treatment allocation was accomplished by computerized random number genera- tors in both centers. Random numbers for the allocation-to-treatment sequence were concealed from the recruiter and the ther- apists carrying out the training. Patients were informed of the 2 possible treatment allocations but blinded to the aims of an experimental versus control condition" "Therapists were not blinded to the treat- ment conditions of the study. However, be- cause both conditions, no performance bias was expected"
Blinding of outcome assessment (detection bias) All outcomes	Low risk	"Both groups were assessed by blinded physical therapists"

Incomplete outcome data (attrition bias) All outcomes	High risk	Dropouts accounted for "Dropout rate in one center was 23% of ini- tially included patients. There was a 10% dropout rate in the other center. Dropout reasons were due to hospital transfer, early discharge, medical complication, or un- specified personal reasons"
Free of systematic differences in baseline characteristics of groups compared?	Low risk	"Lesion site was closely matched in both groups. Mild to moderate sensory dysfunc- tion was present in all middle cerebral artery distribution strokes. Both groups had lower limb spasticity, most pronounced in knee flexors/extensors, plantar flexion, and hip flexors/extensors, as typical for a stage 4 or early stage 3 on the Brunnstrom hemiplegia recovery scale"
Did authors adjust for baseline differences in their analyses?	Low risk	No information provided
Other bias	Unclear risk	No information provided

Torres-Arreola 2009

Methods	Study design: RCT Method of randomisation: "Each patient was randomly allocated to one strategy after they had given written informed consent and completed questionnaires and they were randomised by the coordinator of the study using consecutive opaque envelopes, which were chosen by the patients or their relatives"
Participants	Number of participants: n = 110 Inclusion criteria: "age 40 years or older; diagnosis of first event and ischaemic stroke, mild and moderate neurological damage. Age criterion was decided on frequency and type of stroke, as haemorrhagic type is more frequent in younger patients"
Interventions	 (1) Strategy one (S1) (n = 59) "The team of two trained nurses (see notes) applied one of the two rehabilitation strategies to each patient, beginning 72 hours after initial hospitalisation, when the patient's clinical condition had been stabilised" "The first strategy (S1) included two parts: education and physiotherapy. The education portion consisted of providing information on general care such as feeding, hygiene and mobilisation through a Manual of Physical Rehabilitation for the patient with Stroke and also verbally and through a practical rehabilitation training session provided by the nurse to the caregiver. This was an individual plan of daily rehabilitation according to the stage of Brunnstrom's classification that the caregiver had to perform. The Manual was drafted by the research group, especially for this study. The physiotherapy part of the strategy was designed and applied based on the basal condition of the patients and

Torres-Arreola 2009 (Continued)

	their stage of physical recovery. The latter was defined using the Brunnstrom scale (I-III) , which reflects voluntary activity, movement, coordination, postural stability, muscular tonicity and sphincter control (further details supplied in Table 1). The physiotherapy provided by nurse was divided into three phases. The intensive phase consisted of diup physical therapy initiated at the hospital and continued for two weeks postdischarge through in-home visits. The intermediate phase consisted of bi-weekly in-home visits during the following two weeks (weeks three and four postdischarge). Finally, the support phase consisted of weekly in-home visits during the following three months, up to four months postdischarge" The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising assistive devices, functional task training, musculoskeletal intervention (active) and musculoskeletal intervention (passive) Length of intervention period: four months Number of sessions and length of individual sessions: "average number of visits for the S1 group was 15 and the average duration of each visit had to be about 90 minutes" Intervention provider: nurse (see notes) and caregiver (2) Strategy two (S2) (n = 51) "The second strategy (S2) consisted of education alone. The information and individual plan of rehabilitation provided by the nurse to the patient and caregiver were the same as in the S1 group. This intervention also began at the hospital and was continued in- home with weekly visits" The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising no intervention Length of intervention period: four months Number of sessions and length of individual sessions: "The average number of visits in this group was eight and the average duration of each visit was approximately 45 minutes" Intervention provider: nurse and caregiver This study is classified as intervention (fu
Outcomes	Measures of independence in ADL: Barthel Index Measures of participation: Frenchay Activities Index Other secondary outcome measures: MMSE, Canadian Neurological Scale Time points when outcomes were assessed: "Before randomisation, the patient and/or relatives were interviewed in the hospital to evaluate the patient's basic ADL (Barthel index) and social activities (Frenchay index), which were used as the main outcome variables" "Follow-up measurements of the basic and social ADL and the cognitive state of the stroke patient were obtained at one, three and six months postdischarge"
Notes	Further details on intervention/intervention provider: "Two general nurses received two months of theoretical (80 hours) and practical training (80 hours) in using the interven- tion strategy, as taught by a physical medicine and rehabilitation doctor, a physiother- apist and a specialised nurse. The theoretical part included information about stroke, general aspects of physical rehabilitation, stages of recovery and physiotherapy according to Brunnstrom's stage. The practical part was performed with healthy volunteers and

later with stroke patients in the hospital. In addition, as a product of this phase of the study, the Stroke Rehabilitation Manual for Nurses was elaborated; this had to be used in the rehabilitation strategy. The physical medicine and rehabilitation doctor and physiotherapist established the minimal criteria to consider that the nurse was sufficiently trained to perform physiotherapy"

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	"randomised by the coordinator of the study using consecutive opaque envelopes, which were chosen by the patients or their relatives"
Allocation concealment (selection bias)	Low risk	Consecutive opaque envelopes
Blinding of outcome assessment (detection bias) All outcomes	Low risk	"All outcome variables were gathered by a team of nurses who were different from the intervention team and were blinded to the randomised group allocation"
Incomplete outcome data (attrition bias) All outcomes	High risk	Dropouts accounted for but no explanation given for participants lost to follow-up "Sixty-seven patients (61%) completed the study, five died because of stroke compli- cations and 38 were lost during the follow- up because of other reasons"
Free of systematic differences in baseline characteristics of groups compared?	High risk	"When we compared patients enrolled in S1 vs. S2, we noted increases in the rates of aphasia, dysphasia and/or unconscious- ness, and Brunnstrom's stage I in the pa- tients of group S1" "No differences were found in the patients' characteristics of those who completed the follow-up and those who did not"
Did authors adjust for baseline differences in their analyses?	Unclear risk	No information provided
Other bias	Unclear risk	No information provided

Verheyden 2006

Methods	Study design: RCT Method of randomisation: "Prior to the initial evaluation, participants were divided by simple randomization into an experimental or control group. Randomization was done by a person who was not involved in the assessment or treatment of the patients"
Participants	Number of participants: n = 33 Inclusion criteria: "recruited if they attended the inpatient stroke rehabilitation program and had a hemiparesis that was stroke related. Stroke diagnosis was confirmed by the consultant appointed at the rehabilitation center on the basis of CT or MRI imaging. Patients who suffered from an earlier stroke were only allowed in the study if they were fully recovered" Exclusion criteria: "80 years of age or older, were not able to understand the instructions, had other disorders that could affect motor performance, or obtained a maximum trunk performance score at the start of the study. Trunk performance was evaluated by means of the Trunk Impairment Scale (TIS)"
Interventions	(1) Experimental group (n = 17) "Patients in the experimental and control groups received the conventional multidisciplinary stroke rehabilitation program provided by the rehabilitation center" "In addition to the conventional treatment, patients from the experimental group received 30 minutes of extra training, 4 times a week, for 5 weeks. In total, 10 hours of additional training were given. The additional exercises consisted of selective movements of the upper and lower part of the trunk in supine and sitting. Supine exercises, with the legs bent and the feet resting on the treatment table, included selective anterior-posterior movements of the pelvis, extension of the hips (bridging), and rotation of the trunk initiated from the upper and lower part of the trunk. Exercises in a sitting position included: flexion and extension of the trunk (the patient flexes and extends the trunk without moving the trunk forwards or backwards); flexion and extension of the hips with the trunk extended (with an extended trunk, the movement is initiated in the hips and the patient brings the extended trunk forwards and backwards); lateral flexion of the trunk initiated from the shoulder girdle means that the patient touches the exercise table with one elbow and returns to the starting position, from the pelvic girdle means that the patient moves each shoulder forwards and backwards, from the lower part of the trunk means that the patient moves each shoulder forwards and backwards on an excreise table (the participant shifts the weight from one side to the other and moves forwards and backwards); and finally shuffling forwards and backwards on an excreise table (the participant shifts the weight from one side to the other and moves forwards and backwards on the exercise table). Exercises were gradually introduced and the number of repetitions was determined by the therapist on the basis of the patients' performance" The individual components delivered are listed in Table 3. Based on the individual components delivered are l

Verheyden 2006 (Continued)

	- total of 10 hours of additional training were given"
	Intervention provider: "therapists"
	(2) Control group (n = 16)
	"The conventional treatment program is patient-specific and consists mainly of physio-
	therapy, occupational therapy, and nursing care. Neuropsychological and speech therapy
	are provided if needed. Therapists combine elements from different neurological treat-
	ment concepts but the main emphasis is on the neurodevelopmental treatment concept
	and on motor relearning strategies"
	The individual components delivered are listed in Table 3. Based on the individual
	components, this intervention is categorised as comprising usual care (functional task
	training and neurophysiological intervention)
	Length of intervention period: five weeks
	Number of sessions and length of individual sessions: "mean number of physiotherapy
	sessions = 24; SD = 6; mean number of occupational therapy sessions = 24; SD = 6"
	Intervention provider: "therapists"
	This study is classified as intervention (functional task training, musculoskeletal (active)
	, neurophysiological) versus usual care (functional task training, neurophysiological)
	(Table 5)
_	
Outcomes	Other secondary outcome measures: Trunk Impairment Scale and subscales (static sitting
	balance, dynamic sitting balance and co-ordination)
	Time points when outcomes were assessed: "pre-treatment and post-treatment"
Notes	No data suitable for analysis

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Method of randomisation not described: "divided by simple randomization into an experimental or control group"
Allocation concealment (selection bias)	Low risk	"Randomization was done by a person who was not involved in the assessment or treat- ment of the patients"
Blinding of outcome assessment (detection bias) All outcomes	Low risk	"assessor-blinded randomized controlled trial"
Incomplete outcome data (attrition bias) All outcomes	Low risk	No dropouts "no dropouts during the course of the study, but 2 patients in the experimental group had 3 and 4 fewer hours of addi- tional therapy sessions because of early dis- charge from the rehabilitation center (20 and 21 days after inclusion in the study). In the control group, 3 patients were dis-

Verheyden 2006 (Continued)

		charged after 21, 23, and 25 days, respec- tively. All participants were evaluated be- fore discharge from the rehabilitation cen- ter and included in the analysis"
Free of systematic differences in baseline characteristics of groups compared?	Low risk	"No significant differences were found pre- treatment between the 2 groups for the collected demographic variables, stroke-re- lated parameters, clinical measures, num- ber of therapy sessions received, and pri- mary outcome measure used"
Did authors adjust for baseline differences in their analyses?	Low risk	No information provided
Other bias	Unclear risk	No information provided

Verma 2011

Methods	Study design: assessor-blinded RCT Method of randomisation: "the patients were randomly assigned to either the experi- mental group ($n = 15$) or the control group ($n = 15$) using computer-generated random numbers After the blocks were numbered, a random-number generator program was used to select numbers that established the sequence in which blocks were allocated to either one or the other group. The intervention assignments were enclosed in sealed envelopes, which were opaque and sequentially numbered. A resident physician at the study site conducted the random-number program. However, the resident physician was blinded to the research protocol and was not involved in the trial"
Participants	Number of participants: n = 30 Inclusion criteria: first episode of unilateral stroke with hemiparesis during the last month, functional ambulation classification level II and above, ability to understand instructions (Hindi Mental State Examination [HMSE] > 24), ambulatory before stroke, ability to cope with the intensive training programme, ability for mental imaging (Movement Imagery Questionnaire-revised second version [MIQ-RS] \geq 25) and National Institutes of Health Stroke Scale (NIHSS) score < 14 Exclusion criteria: history of any other neurological pathology such as Parkinson disease and epilepsy, conditions affecting balance, neglect, dementia, impaired vision, impaired conscious level, concomitant medical illness, musculoskeletal conditions affecting lower limbs, cardiovascular instability (resting systolic blood pressure > 200 mm Hg and resting diastolic blood pressure > 100 mm Hg) and/or serious cardiac conditions (hospitaliza- tion for heart disease within three months, active angina, serious cardiac arrhythmias, hypertrophic cardiomyopathy, severe aortic stenosis)
Interventions	 (1) Experimental group (n = 15) "The program included different workstations and was intended to improve the meaningful tasks related to walking competency, such as balance control, stair walking, turning, transfers, and speed walking. Further, each session consisted of a continuous practice

of standing and walking-related tasks on specified workstations with a minimal break" "Motor imagery comprised imagining walking abilities and tasks related to a real-life situation" The individual components delivered are listed in Table 3. Based on the individual
components, this intervention is categorised as comprising functional task training Length of intervention period: two weeks
Number of sessions and length of individual sessions: "15 minutes of motor imagery followed by 25 minutes of task-oriented circuit class training for a total of 40 minutes, 7 days per week for 2 weeks (14 sessions)"
Intervention provider: "Task-oriented circuit class training was provided to groups com- prising up to 4 patients at any one time with a physiotherapist or occupational therapist for supervision"
(2) Control group (n = 15)"Conventional post stroke lower extremity rehabilitation program based on the Bobath's neurodevelopmental technique"
The individual components delivered are listed in Table 3. Based on the individual com- ponents, this intervention is categorised as comprising neurophysiological intervention Length of intervention period: two weeks
Number of sessions and length of individual sessions: "The control group program was matched for duration, number, and frequency of the sessions with the experimental group program"
Intervention provider: not stated This study is classified as active intervention one (functional task training) versus active intervention two (neurophysiological) (Table 6)
Measures of independence in ADL: Barthel Index Measures of voluntary movements: Functional Ambulation Classification, Rivermead Visual Gait Assessment, 10-Metre Walk test, Six-Minute Walk test, step length, stride length, step width and cadence Time points when outcomes were assessed: "All the participants were assessed using the outcome measures at baseline (preintervention), week 2 (postintervention) except for
Barthel Index (BI), and at week 6 (follow-up)"

Notes

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	"Computer-generated random numbers. After the blocks were numbered, a ran- dom-number generator program was used to select numbers that established the se- quence in which blocks were allocated to ei- ther one or the other group. The interven- tion assignments were enclosed in sealed envelopes, which were opaque and sequen- tially numbered"

Verma 2011 (Continued)

Allocation concealment (selection bias)	Low risk	"A resident physician at the study site conducted the random-number program. However, the resident physician was blinded to the research protocol and was not involved in the trial"
Blinding of outcome assessment (detection bias) All outcomes	Low risk	"The experimental and control interven- tions were given by 2 independent thera- pists. The subjects were blinded for inter- vention of interest"
Incomplete outcome data (attrition bias) All outcomes	Low risk	Dropouts accounted for (One participant was lost to follow-up, from the experimental group because of a second stroke)
Free of systematic differences in baseline characteristics of groups compared?	Low risk	"The groups did not significantly differ in any of the demographic and baseline clini- cal characteristics"
Did authors adjust for baseline differences in their analyses?	Low risk	No information provided
Other bias	Unclear risk	No information provided
Wade 1992		
Methods	Study design: RCT Method of randomisation: permuted blocks of 10, using random number tables	
Participants	Number of participants: n = 94 Inclusion criteria: first stroke more than one year previously and mobility problems (fall within last three months, used a walking aid, limited mobility or slow gait speed)	
Interventions	 (1) Mixed (problem solving, community physiotherapy) (n = 49) "Problem solving' approach: patients were assessed with particular reference to their mobility, and problem areas were identified. Realistic, achievable goals were discussed with the patient and carers and then the physiotherapist intervened if required" Re-education of abnormal components of gait Practice walking inside and outside For standing balance: exercises to stimulate reactions, obstacle courses, practice on uneven surfaces Reeducation of sitting to standing Equipment: removal, provision, maintenance, adjustment Activities of daily living: advice, referral to community occupational therapist Demonstrate participant's ability to participant/carer Graduated exercise programme The individual components delivered are listed in Table 3. Based on the individual com- 	

	ponents, this intervention is categorised as comprising assistive devices, cardiopulmonary
	intervention and functional task training
	Length of intervention period: not stated
	Number of sessions and length of individual sessions: range one to 11 visits, mean number
	of visits = four (standard deviation 2.5). Time (including travel and administration)
	ranged from one hour 10 minutes to three hours 10 minutes
	Intervention provider: physiotherapist and occupational therapist
	(2) No treatment $(n = 45)$
	The individual components delivered are listed in Table 3. Based on the individual
	components, this intervention is categorised as comprising no intervention
	Length of intervention period: no intervention
	Number of sessions and length of individual sessions: no intervention
	Intervention provider: no intervention
	This study is classified as intervention (functional task training) versus no treatment
	(Table 4). The intervention group also received assistive devices and cardiopulmonary
	intervention
	mice vention
Outcomes

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Permuted blocks of 10, using random num- ber tables
Allocation concealment (selection bias)	Low risk	No information provided
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Participant not blinded-not possible Therapist not blinded-not possible Assessor was blinded
Incomplete outcome data (attrition bias) All outcomes	Unclear risk	Dropouts accounted for 89/94 completed intervention and had three-month follow-up All participants included in the analysis un- less they died or had not reached last fol-

Wade 1992 (Continued)

		low-up point For some outcomes (e.g. gait speed), num- bers are less because not all could perform the test
Free of systematic differences in baseline characteristics of groups compared?	Unclear risk	No information provided
Did authors adjust for baseline differences in their analyses?	Unclear risk	No information provided
Other bias	Unclear risk	Initial recruitment was from final fol- low-up from Oxford Community Stroke Project, but not enough participants were recruited. Additional participants were re- cruited by contacting a rehabilitation cen- tre, asking general practitioners, making a radio appeal and contacting community workers and through self referral. Partici- pants recruited from the Oxford Commu- nity Stroke Project were less disabled than those recruited in other ways. However, the two groups were similar at randomisation

Wang 2004a

Methods	Study design: RCT Method of randomisation: according to the assessment time, in a 2:1 (rehabilitation: control) ratio
Participants	Number of participants: n = 105 (at recruitment); n = 98 (data available after treatment) Inclusion criteria: "Aged between 42-78 years old, commenced therapy (approximately) within 3 days of stroke onset, satisfied the 1995 Fourth National Conference on Cerebral Vascular Disease classification guidelines and stroke as confirmed by CT or MRI scan" Exclusion criteria: "Stroke onset exceeding 1 week and severe impaired cognitive and/or speech issues"
Interventions	(1) Rehabilitation group (n = 70 before dropout; n = 66 (data available: see Table 5) "Both groups received conventional treatment during the critical period, with treatment group commencing early-stage physical rehabilitation once medically stable. Based on the condition of each patient, a treatment plan was developed prior to treatment. Treat- ment method utilised exercise therapy, including techniques and equipment, locations included bedside and treatment room, treatment was conducted by therapist. Mainly utilised motor relearning methods, including: (i) Positioning of healthy limbs. (ii) Passive ranging exercises on joints of limbs on affected side. (iii) Functional training of upper limbs, including stimulation of muscle motion as well as training of control of extension, separation of fingers, prevention of contracture, etc. (iv) Training of rolling on bed, as well as training of lying to bedside sitting, training of bedside sitting balance, sit-to-stand

Wang 2004a (Continued)

Risk of hias	
Notes	Original study translated from Chinese to English
Outcomes	Measures of motor function: Fugl-Meyer Assessment (upper limb, lower limb) Other secondary outcome measures: somatosensory evoked potential (SEP) Time points when outcomes were assessed: "Each patient, within 2 days of being med- ically stable, would undergo 1st assessment, and 30 days later would undergo the 2nd assessment"
	 training. (v) Upright training (bed). (vi) Bedside standing and sitting training as well as bedside standing balance training. (vii) Gait training. (viii) Weight-bearing and weight-assisted training, etc. Throughout entire treatment period, emphasis on correct training posture and relaxation training of spastic muscles, anti-spasticity techniques and muscle training of non-spastic muscles. Family members were taught the correct complementary training and care methods, while concurrently focusing on psychological treatment, during the course of the training, frequently use language that will boost the patient's confidence in recovery" The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising functional task training and musculoskeletal intervention (passive) Length of intervention period: 30 days Number of sessions and length of individual sessions: one to two/d, 45 minutes/session, with exercise time and intensity reduced as appropriate if participant lacked the capability Intervention provider: therapist (2) Control group (n = 35 before dropout, n = 32 data available: see Table 5) "Received conventional treatment during the critical period but did not receive any rehabilitation treatment" The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising no intervention Length of intervention provider: therapist (2) Control group (n = 35 before dropout, n = 32 data available: see Table 5) "Received conventional treatment during the critical period but did not receive any rehabilitation treatment" The individual components delivered are listed in Table 3. Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	"According to the assessment time, in a 2: 1 (rehabilitation:control) ratio"-no further details provided
Allocation concealment (selection bias)	Unclear risk	No information provided
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Blinded outcome assessment

Incomplete outcome data (attrition bias) All outcomes	Low risk	Dropouts accounted for Dropouts due to financial reasons or inabil- ity to adhere to study design ($n = 4$ drop- outs in the rehabilitation group and $n = 3$ in the control group)
Free of systematic differences in baseline characteristics of groups compared?	Low risk	No significant baseline differences
Did authors adjust for baseline differences in their analyses?	Low risk	No information provided
Other bias	Unclear risk	No information provided
Wang 2004b		
Methods	Study design: RCT Method of randomisation: not stated	
Participants	Number of participants: n = 50 Inclusion criteria: "Satisfied the 1995 Fourth National Conference on Cerebral Vascular Disease classification guidelines, confirmed by CT or MRI scan, first ever stroke, within 4 months since stroke onset, spastic hemiplegic limbs and between 1-3 for Ashworth assessment" Exclusion criteria: "Impairment in consciousness, psychology, cognition, agnosia, apraxia, Parkinson's disease, epilepsy, electrolyte imbalance, cardiac pacemaker, severe malnutrition, severe cardiorespiratory disease and participants with poor adherence"	
Interventions	(1) Treatment group (n = 25) "Both groups were given routine drug treatment and basic rehabilitative training, looking over brain circulation, anti-coagulation, nutrition and rest, electrolyte balance, preven- tion of various secondary complications; maintaining optimal limb positioning, passive and active joint range of motion, tissue massage etc. Patients in the treatment group had additional neural facilitation combined with the use of the muscular spasm machine, following the characteristics of the stages of spasticity. Prior to neural facilitation, patients had to undergo relaxation. Neural facilitation training included prone positioning, slow traction to relax tensed muscles; striking spastic muscles including both agonists and antagonists to restore the appropriate muscular balance; traction to muscles and gentle striking to the muscle belly, guiding the affected limbs to exercise, so as to stimulate a bal- ancing reaction, overcoming over activated muscles and compensatory movements; using co-contraction principles, allowing resistive forces exerted during flexion and extension of the non-affected upper limb to illicit flexion and extension of the affected upper limb, and assisting or encouraging the patient to actively flex and extend the limb; making use of asymmetric tonic neck reflex mechanisms, reducing the tone in both upper and lower limbs and stimulating limb movement by rotating the patient's neck, holding on to the lower limbs while moving them with momentum, or through reverse action by moving the non-affected shoulder and elbow joints rhythmically so as to reduce muscle tension;	

Wang 2004b (Continued)

	making use of body weight to optimise ankle joint integrity; stretching the thumb and externally rotating the forearm to reduce tension in the wrist joint and finger flexors; using cold and hot sensations etc to stimulate and activate contraction of relevant muscles, suppress spasticity etc, compressing the joint to reduce tension, reducing spasticity etc. Low-frequency pulse current treatment: using a Beijing manufactured KX-3A model for spasticity treatment" The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising modality, musculoskeletal intervention (passive) and musculoskeletal (active) and neurophysiological intervention Length of intervention period: four weeks Number of sessions and length of individual sessions: 30 to 45 minutes/session, one session/d, five/wk Intervention provider: doctor, nurse (2) Control group (n = 25) "Both groups were given routine drug treatment and basic rehabilitative training, looking over brain circulation, anti-coagulation, nutrition and rest, electrolyte balance, prevention of various secondary complications; maintaining optimal limb positioning, passive and active joint range of motion, tissue massage etc." The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as usual care (musculoskeletal intervention (passive)) Length of intervention period: not stated Number of sessions and length of individual sessions: not stated Intervention provider: not stated This study was classified as intervention (musculoskeletal (active), musculoskeletal (passive), neurophysiological) versus usual care (musculoskeletal (passive)) (Table 5). The intervention group also received modality
Outcomes	Measures of motor function: Fugl-Meyer Assessment Measures of tone or spasticity: Ashworth Scale
	Time points when outcomes were assessed: at enrolment and after four weeks of inter- vention
Notes	Original study translated from Chinese to English

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	No information provided
Allocation concealment (selection bias)	High risk	Study implementation by authors
Blinding of outcome assessment (detection bias) All outcomes	High risk	Outcome assessment by authors

Wang 2004b (Continued)

Incomplete outcome data (attrition bias) All outcomes	Low risk	No dropouts
Free of systematic differences in baseline characteristics of groups compared?	Low risk	No significant baseline differences
Did authors adjust for baseline differences in their analyses?	Low risk	No information provided
Other bias	Unclear risk	No information provided
Wang 2005		
Methods	Study design: RCT Method of randomisation: stratified into " two or three) and "patients with relative red Sealed envelopes, independent person	⁶ patients with spasticity" (Brunnström stage covery" (Brunnström stage four or five)
Participants	Number of participants: n = 44 Inclusion criteria: "Hemiparesis secondary to CVA, LE Brunnström motor recovery 2 to 5 and able to communicate and co-operate"	
Interventions		

Wang 2005 (Continued)

	Intervention provider: physical therapists This study is classified as active intervention one (neurophysiological) versus active inter- vention two (functional task training, musculoskeletal (active), musculoskeletal (passive)) (Table 6)
Outcomes	Measures of functional independence: MAS, Stroke Assessment Impairment Set Measures of postural control and balance: Berg Balance Scale Measures of spasticity/tone: Stroke Assessment Impairment Set (SAIS, tone) Time points when outcomes were assessed: "The patients were assessed twice: once before and once after treatment"
Notes	

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	"Sealed envelopes, independent person. The random assignment was achieved by an independent person who chose one of the sealed envelopes 30 min before the start of the intervention"
Allocation concealment (selection bias)	Low risk	Independent person
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Participant not blinded Therapist not blinded Assessor was blinded: "Test results for each patient were assessed and evaluated by a separate physical therapist who was not in- volved in the treatment programme and did not know about the patient's group"
Incomplete outcome data (attrition bias) All outcomes	Low risk	No dropouts
Free of systematic differences in baseline characteristics of groups compared?	Unclear risk	Baseline characteristics are reported but are not compared statistically. Unclear whether the groups were similar at baseline for all characteristics
Did authors adjust for baseline differences in their analyses?	Unclear risk	No information provided
Other bias	Unclear risk	Participants were all inpatients and pre- sumably were able to see the treatment given to participants in the other treatment group, which is a potential source of con- tamination

Different therapists did apply the two interventions (four therapists in total), so different aspects related to their personal delivery of the intervention could be a potential confounder. However, it is not clear whether two therapists each applied one intervention or whether all four therapists applied both interventions

Wang 2006	
Methods	Study design: RCT Method of randomisation: not stated
Participants	Number of participants: n = 80 Inclusion criteria: "Satisfied the 1995 Fourth National Conference on Cerebral Vascular Disease classification guidelines, confirmed by CT or MRI scan as first ever stroke, medically stable within 3 weeks after stroke onset, Glasgow Coma Scale > 8, aged 40-80 years old and deficits in limb function" Exclusion criteria: "Active liver, kidney disease(s), paraplegia, deaf, mute, unable to ac- commodate assessment and inaccessible homes"
Interventions	 (1) Rehabilitation group (n = 40) "Both groups of patients received conventional clinical treatment and care. Treatment group besides receiving conventional clinical treatment, also strictly followed 'fifteen' research topic 'cerebrovascular disease 3-phase rehabilitation intervention' to undergo rehabilitative training. On entering the group, treatment group patients immediately commenced phase 1 rehabilitative treatment plan (in neurology ward), including antispasticity positioning on bed; breathing exercises; passive ranging exercises on each joint on affected side; nerve and muscle stimulation technique (mainly Rood technique and Brunnstrom technique); active ranging exercises of healthy limbs; lying to sitting training; sitting balance training; ADL training on bed, etc" "With progression of time, patients' physical ability gradually improved, and were transferred from neurology to rehabilitation zone to undergo rehabilitative treatment, i.e., phase 2 rehabilitative treatment, with continued strengthening of phase 1 rehabilitation measures as per the patient's condition; sit to stand training; transference training; deployment of nerve and muscle stimulation techniques (mainly Bobath technique and PNF technique); standing balance training; affected limbs weight-bearing training; gait training and stair-climbing training, while concurrently inserting appropriate occupational therapy" "After a period of phase 2 rehabilitative treatment, most patients were discharged to their homes or community to continue rehabilitative treatment, i.e. phase 3 rehabilitative treatment. Mainly involved therapist making regular house visits to provide guidance, help patient to undergo required functional training, until the course of disease has reached 6 months mark" The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising functional task training and musculoskeletal intervention (passive), neuroph

Wang 2006 (Continued)

	Length of intervention period: till six months after stroke Number of sessions and length of individual sessions: not stated Intervention provider: therapists (2) Control group (n = 40) "Received clinical treatment and unguided self-training. The control group did not do any standard rehabilitative training" The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising no intervention Length of intervention period: no intervention Number of sessions and length of individual sessions: no intervention Intervention provider: no intervention This study is classified as intervention (functional task training, musculoskeletal (passive) , neurophysiological) versus no treatment (Table 4)
Outcomes	Measures of tone or spasticity: Modified Ashworth Scale Other secondary outcome measures: Brunnstrom Time points when outcomes were assessed: on enrolment, one month after stroke, three months after stroke and six months after stroke
Notes	Original study translated from Chinese to English No data suitable for analysis

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	No information provided
Allocation concealment (selection bias)	Unclear risk	No information provided
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Outcome assessors were not involved in de- livering the intervention, but it is not clear whether they were blinded to allocation of groups
Incomplete outcome data (attrition bias) All outcomes	Unclear risk	No dropouts described
Free of systematic differences in baseline characteristics of groups compared?	Low risk	No significant baseline differences
Did authors adjust for baseline differences in their analyses?	Low risk	No information provided
Other bias	Unclear risk	No information provided

Methods	Study design: RCT Method of randomisation: not stated ("80 cases were randomly [divided] into 2 groups, control and training group")
Participants	Number of participants: n = 80 Inclusion criteria: "CVA suffers within 3 months after onset with no obvious cognitive problems (able to follow the instructions) and no previous mobility limitations"
Interventions	 (1) Exercise group (n = 40) "each group received physical therapyselective trunk activities were emphasized in exercise group as well" "The intervention was basically Bobath orientated, the experimental group focused on exercises of trunk activities (based on PM Davis "Right in the middle" Springer-Verlag New York 1990)" "Both groups received rehabilitation retraining. The 'training' group emphasized on truncal training. In supine: a chest support exercises: participant leaning forward, therapist placed hands on both sides of chest, compressing inwards and downwards by following the breathing rhythm. B. facilitating abdominal breathing exercises. C. lower truncal rotation. D. supine to prone position. E. shifting between sitting and supine position. In sitting: a sitting on the therapy bed, participant hugged knees with both hands and rocked forwards and backwards. B. sitting on bed with knee extended, both hands touching the knees (therapists gently hold on to participants' hands, adding in truncal rotation while lying down. D. sitting on a stool, both hands hugging the shoulders, hip move accordingly. E. sitting on a stool, add in truncal rotation. F. sitting on a stool, Place non-affected ankle to affected knee, both hands clasped to touch non-affected knee, shift bodyweight left and right" "In standing: a. Standing in front of a table the same height as the hips, both arms crossed, both shoulder blades leaning on table, slowing raise shoulders till straight. B. both hands clasped to raise ball from different heights. C. facing the wall, both hands clasped to draw arcs. D. Standing facing the therapist, push shoulders against therapist's hands. Using therapy ball to train truncal flexion and extension, rotation and side flexion" The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising neurophysiological Length of intervention period: 12 weeks (mean 68 days) Nu

Wellmon 1997

Methods	Study design: RCT Method of randomisation: not stated
Participants	Number of participants: n = 21 Inclusion criteria: disorder of unilateral movement in lower limb, CVA less than 150 days previously, able to stand unsupported for longer than 30 seconds, able to walk farther than 7 m, able to understand visual/verbal commands, medically stable enough for 20 minutes of treatment, more than zero degrees passive ankle dorsiflexion and no hip, knee, ankle, foot pain
Interventions	(1) Motor learningRepetitive practice of context-specific taskRepetitive practice of stepping taskThe individual components delivered are listed in Table 3. Based on the individual

Wellmon 1997 (Continued)

Notes	No outcomes included in analysis
Outcomes	Measures of postural control and balance: standing symmetry; step length symmetry; single stance symmetry
	components, this intervention is categorised as comprising functional task training Length of intervention period: two days Number of sessions and length of individual sessions: addition of 20 minutes, twice a day for two days. Participants had received routine physiotherapy, based on motor learning principles, although no routine physiotherapy was given on the two days of the intervention Intervention provider: not stated (2) Control (no treatment) The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising no intervention Length of intervention period: no intervention Number of sessions and length of individual sessions: Participants had received routine physiotherapy, based on motor learning principles, although no routine physiotherapy was given on the two days of the intervention Intervention provider: no intervention This study is classified as intervention (functional task training) versus no treatment (Table 4)

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	"were randomly assigned to either treat- ment or control group." No further details
Allocation concealment (selection bias)	Unclear risk	No information provided
Blinding of outcome assessment (detection bias) All outcomes	High risk	Participant not blinded Therapist not blinded Assessor not blinded
Incomplete outcome data (attrition bias) All outcomes	Low risk	No dropouts
Free of systematic differences in baseline characteristics of groups compared?	Unclear risk	No information
Did authors adjust for baseline differences in their analyses?	Unclear risk	No information
Other bias	High risk	The amount of treatment was very limited (four sessions over two days); this may have been insufficient to effect a change

Wu 2006

Methods	Study design: RCT Method of randomisation: randomisation based on enrolment time
Participants	Number of participants: n = 100 Inclusion criteria: ischaemic or haemorrhagic stroke participants identified from the 1995 Fourth National Conference on Cerebral Vascular Disease classification guidelines, confirmed by CT or MRI scan as first ever stroke, provided informed consent, medically stable within 24 hours after stroke onset, Glasgow Coma Scale score > eight, aged 40 to 80 years old with deficits in limb function
Interventions	 (1) Rehabilitation group (n = 50) "Received clinical treatment and regular rehabilitation training. Standardised rehabilitation training commenced after the patients were cognitively and medically stable for 48 hours with no aggravation of existing stroke symptoms (within 21 days of stroke, as stage 1 rehabilitation); rehabilitation treatment from early recovery to transfer to Rehabilitation (e.g. home ward) from middle to late recovery (within 4-6 months after stroke, as stage 3 rehabilitation), with the following method: Prevention and treatment of spasticity: (i) appropriate positioning. (ii) Bobath method of holding hands: both hands intertwined, use the non-affected fingers to lock the affected fingers, with the affected thumb at the top, stretch forward, flex shoulders, lift arms to touch the forehead, hold for a few seconds before returning to original position, practising multiple times daily. (iii) active stretch: extend affected fingers, place 20cm from body on a support, use body weight to stretch spastic muscles, for 3-5minutes per stretch, practising multiple times daily. (iv) Traction: apply traction techniques to affected spastic joints, on feeling resistance, continue with technique for at least 2-3 minutes on the same spot, relax, and repeat. (v) standing bed training: stand on a sloped plank in front of a ladder wall, correct foot inversion and foot, target lower limb spasticity, 5-8 minutes daily. (vi) critical control of Bobath technique, PNF's technique of upper limb stretch and lower limb flexion; both tonic labyrinthine reflex and the asymmetrical tonic neck reflex were also used in the rehabilitation process" "On top of preventing and treating spasticity, appropriate therapy was given depending on the stroke phase, including: rolling practice on bed, bridging practice, lying to sitting and sitting balance training, ADL practice, manual therapy, speech and language therapy, psychological counselling" The individual components delivered are list

Wu 2006 (Continued)

	Number of sessions and length of individual sessions: not stated Intervention provider: not stated This study is classified as intervention (functional task training, musculoskeletal (active) , musculoskeletal (passive), neurophysiological) versus no treatment (Table 4)
Outcomes	Measures of independence in ADL: Modified Barthel Index Measures of motor function: Fugl-Meyer Assessment Measures of tone or spasticity: Modified Ashworth Scale Time points when outcomes were assessed: "pre-treatment' and after 6 months of inter- vention"
Notes	Original study translated from Chinese to English

Yan 2002

Methods	Study design: RCT Method of randomisation: not stated
Participants	Number of participants: n = 78 Inclusion criteria: not stated
Interventions	(1) Rehabilitation group (n = 40) "Both groups of patients received conventional neurological drug treatment, treatment group after initial assessment commenced rehabilitative treatment procedure. The reha- bilitative training procedure was as follows: based on the extent of the patient's hemi- plegia and affected limbs' functional status, procedure was divided into 3 phases: early phase, rehabilitative treatment on bed, and rehabilitative treatment after leaving the bed" "(i) Early phase: commenced 48 h after patient was medically stable and neurological symptoms stopped progressing. Healthy limbs: therapists should be familiar with posi- tioning of healthy limbs, and let family members understand the reason for doing so and to master these techniques. Upper limb: a pillow slightly higher than torso was placed below extended upper limb and maintained upper limb in supine position; Pelvis and lower limb: those with tendency for lower limb to buckle, while in lying position should have a pillow supporting the affected side of the limb to prevent excessive flexion. Pillows were used to prevent excessive abduction, external rotation. Participants with excessive ankle curvature or inversion used a splint board for positioning. Passive joint range of motion: from distal to proximal, 10x/joint, 2/day. Movement should be of ease, of short

duration, used Brunnstrom technique's rapid traction, stimulation through overpressuring of joints, 2/day, 15min/session"

"(ii) rehabilitative treatment on bed: This phase commenced when participants possessed good sense of awareness and communication ability: using Bobath method of holding hands, with elbow extension, shoulder elevation to 90 degrees, using both upper limbs to lead during rolling, before turning the hips. After gaining independence in rolling, participants can commence bridging exercises, ankle dorsiflexion exercises. Sitting up from bed training: increase angle of bed to 30 degrees, once participants could tolerate longer than 30mins in the angle, the angle of bed is increased by 10 degrees, until participants can maintain at 90 degrees for 30 mins. Lying to sitting and sitting balance training. The above were practised 2/day, 30 min/session, increasing to 3-4/day if participants had no discomfort"

"(iii) Rehabilitative treatment after leaving the bed: In the rehabilitation centre, standing upright training -> forward, backward, left and right weight shifting training -> training by using the affected lower limb to support (single leg standing) -> limb loading of the affected lower limb (rising training, sitting down training, sit to stand training) -> ankle dorsiflexion -> anterior, posterior pelvic tilt training -> gait training with pelvic stabilisation (parallel bar -> flat ground -> slope -> stairs), 2/day, 1hr/session. Average length of treatment: 38 days"

The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising assistive devices, functional task training and musculoskeletal intervention (passive)

Length of intervention period: 38 days

Number of sessions and length of individual sessions: session length dependent on technique applied (see above)

Intervention provider: not stated

(2) Control group (n = 38)

"Received conventional neurological drug treatment but did not receive any standard rehabilitative treatment"

The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising no intervention

Length of intervention period: no intervention Number of sessions and length of individual sessions: no intervention

Intervention provider: no intervention

This study is classified as intervention (functional task training, musculoskeletal (passive)) versus no treatment (Table 4). The intervention group also received assistive devices

Outcomes	Measures of Independence in ADL: Barthel Index Other secondary outcome measures: Brunnstrom, three-level balance rating Time points when outcomes were assessed: within 24 hours before start of intervention and on the last day of intervention

Yelnik 2008		
Methods	Study design: "Prospective, multicenter, randomised parallel-group trial with a single- blind evaluation" Method of randomisation: "After patients gave informed consent, the trial statistician generated the randomisation sequence using random number tables. Randomization was stratified by center"	
Participants	Number of participants: n = 68 Inclusion criteria: "Hemiplegia after a single hemispheric stroke due to an infarct or hemorrhage shown by computerized tomography or magnetic resonance imaging within 3 to 15 months prior to entry, at onset of stroke, subjects had to be unable to walk for at least 2 weeks, but not exceeding 3 months. Walking was defined as the ability to walk at least 50 meters with an orthosis or cane if needed (but without human assistance). Aged less than 80 years old, ambulatory, and living at home" Exclusion criteria: "a previous history of walking disorder, cognitive disorders that pre- vented comprehension of the rehabilitation program, and history of a vestibular disor- der"	

(1) NDT-based treatment (n = 35)

Interventions

"Based on global sensory motor rehabilitation derived from the neurodevelopmental concepts described by Bobath, more attention paid to the quality of the gesture and gait control, the spasticity, and abnormal movement inhibition than to the quantity of exercise and an increase of the difficulty from one session to another depending on the ability of the patients"

"Sessions 1 to 4: Exercises conducted on the Bobath platform, weight shifting, waist dissociation, pelvis control, crawling, turning over, four footing, and standing on the knees. Sessions 5 to 8: Exercises on the edge of the platform in sitting position, transfers

from lying to sitting, sitting to standing, sitting on the platform to a chair, upper limb used for bearing. Analytic exercises for upper limb were associated for a maximum of one third of the session. Sessions 9 to 20: Walking in the corridor and on the steps, control of the weight bearing and shifting, quality of the heel strike, knee control, and waist dissociation"

"During the 20 sessions, visual deprivation, head movements, or training with unstable bases of support were forbidden for the progression of exercise difficulties"

The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising functional task training and neurophysiological intervention

Length of intervention period: "Physical therapy had to begin within 7 days, and conducted 5 days a week for the following 4 weeks"

Number of sessions and length of individual sessions: total of 20 successive sessions conducted five days a week

"Each session lasted 60 to 70 minutes, depending on the rest required, and included 5 minutes for spasticity inhibition, 40 to 45 minutes of exercises specific to the session, 10 to 20 minutes of rest distributed throughout the session, and related to need"

Intervention provider: not stated

(2) Multisensorial (n = 33)

"Physical rehabilitation based on the manipulation of the sensory information required to maintain balance, attention being paid to the amount of exercise, that is, duration and intensity, rather than the quality of the movement. Most of the exercises were conducted in visual deprivation, thus challenging the selection and synthesis by the brain of vestibular and somatosensory information"

"Each type of exercise was related to the patient's progress, with progression under visual control for repetition of the exercises, then as much under visual deprivation as possible, and using unstable planes and foam ground-sheet, tilting the head back, rightward and leftward. The duration of the exercises under visual deprivation was not exactly fixed and took approximately half of the session"

"The exercises had to be repeated for patients to learn them and moreover improve their performance in terms of duration or intensity by slowly increasing the difficulty. There were 4 types of modalities, conducted as follows: sessions 1 to 4, modality 1; sessions 5 to 8, modality 2; sessions 9 to 20, by alternating modality 3 once and modality 4 twice. Modality 1: On the foam Bobath platform, four footing, standing on the knees, anteroposterior and lateral weight shifting, moving objects with the upper limb, external destabilization. Modality 2: Sitting on the edge of the platform and sitting on a ball, weight shifting, upper limb movements, moving objects with the upper limb, external destabilizations. Modality 3: Static standing with feet together, tandem position, one foot standing, control of weight shifting, moving objects with upper limbs, external destabilizations. Modality 4: Walking with movements of the upper limbs, while speaking, with external destabilization, walking laterally and backward, 10 minutes of treadmill training without upper limb support, opening eyes at various speeds, closing eyes at constant speed. In each modality, the variations that can be used were head movements, foam support, unstable platform, rolling skate, irregular floor, and constant visual deprivation" The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising functional task training Length of intervention period: "Physical therapy had to begin within 7 days, and conducted 5 days a week for the following 4 weeks"

Physical rehabilitation approaches for the recovery of function and mobility following stroke (Review) Copyright © 2014 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

	Number of sessions and length of individual sessions: total of 20 successive sessions conducted five days a week "Each session lasted 60 to 70 minutes, depending on the rest required and included 5 minutes for spasticity inhibition, 30 to 35 minutes to specific modalities, 10 minutes of walking and stepping, and 10 to 20 minutes of rest distributed throughout the session" Intervention provider: not stated This study is classified as active intervention one (functional task training, neurophysiological) versus active intervention two (functional task training) (Table 6)
Outcomes	Measures of independence in ADL: Functional Independence Measure Measures of postural control and balance: Berg Balance Scale, posturographic limits of stability Measures of voluntary movements: speed of walking, percentage of double-stance phase, time to climb 10 steps and return, daily time of walking (minutes) Measures of quality of life and social isolation: Nottingham Health Profile Other secondary outcome measures: security sensation during walking, number of falls since stroke Time points when outcomes were assessed: "The first visit for evaluation (day 0 [D0]) was conducted by one of the blinded evaluators. Posttreatment evaluation (day 30 [D30]) was carried out within 7 days of the end of the physical rehabilitation program. The second posttreatment evaluation (day 90 [D90]) was carried out 3 months after the first evaluation"
Notes	"Sixty-seven of the 68 enrolled patients completed the study but the analysis, conducted for intention to treat, included all of the patients: 35 in the NDT group and 33 in the multisensorial group" Data not suitable for analysis

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	"trial statistician generated the randomiza- tion sequence using random number ta- bles. Randomization was stratified by cen- ter"
Allocation concealment (selection bias)	Low risk	By trial statistician
Blinding of outcome assessment (detection bias) All outcomes	Low risk	"the first visit for evaluation (day 0 [D0]) was conducted by one of the blinded eval- uators"
Incomplete outcome data (attrition bias) All outcomes	Low risk	Dropouts accounted for "In the NDT-based group, 1 patient had to stop after 5 sessions of physical ther- apy for carotid surgery, which had not been planned. He could not be assessed. In the multisensorial group, 1 patient was lost to

Yelnik 2008 (Continued)

		follow-up between D30 and D90 and an- other because of an adverse event unrelated to the treatment"
Free of systematic differences in baseline characteristics of groups compared?	Low risk	"no differences were found at entry be- tween groups"
Did authors adjust for baseline differences in their analyses?	Low risk	No information provided
Other bias	Unclear risk	Deviations from protocol reported "Two patients had fewer than 16 physical therapy sessions (12 and 15), but they could be assessed at D30 and D90. For 6 patients, the time lag for the first assessment was longer than 45 days (46, 47, $2 \cdot 48$, and $2 \cdot 49$ days)"
Yin 2003a		
Methods	Study design: RCT with three groups Method of randomisation: not stated "among them, randomly selected 30 persons as the rehabilitation group, and another 30 randomly selected persons were grouped into rehabilitation with intermediate frequency"	
Participants	Number of participants: n = 90 Inclusion criteria: "All the patients selected were coincident with the diagnosis criteria of the second national cerebral vascular disease conference and diagnosed by CT or MRI. The patients had a stable life signs and were 2 weeks after stroke" Exclusion criteria: "abnormal in liver, kidney, heart and lung function"	
Interventions	(1) Rehabilitation group (n = 30) "the routine drugs in three groups were same" "Patients in the rehabilitation group were administered with rehabilitation exercise and general education of rehabilitation" "We employed Bobath method on hemiplegia extremities. Pay attention to the position of the suffered extremities. When the patients lying on the healthy side, suffered upper limb were padded with a pillow and the upper limb were straight, with center of the palm down. The wrists were lifted with a pad. When the patients lied with the suffered side, suffered should extended forward, elbow extended and center of the palm down. For cases with the increased strength in flexor muscle, finger differentiation board or pad [was] put in the center of the hand and keep the finger straight forward as much as possible. The lower [limbs] were lightly flexioned, with back of the foot and lower leg [kept] perpendicular as much as possible. When the patients lying with back, suffered upper limb were in lightly extension conditions, with elbow lightly flexed, support shoulder and hand with pad to keep center of the palm up and keep upper limb posterior rotation position to prevent scapula down and dislocation of shoulder joint. Lower limb, pelvis and hip were supported with pad to keep perpendicular conditions between back of the	

	foot and lower legTurn exercise, sitting exercise and standing exercise were according to regulations of Bobath adult hemiplegia exercise" The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising assistive devices, functional task training, musculoskeletal intervention (passive) and neurophysiological intervention Length of intervention period: not stated Number of sessions and length of individual sessions: "rehabilitation therapy lasted for 40 min with once a day" Intervention provider: not stated (2) Rehabilitation with therapy with intermediate frequency (n = 30) The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising assistive devices, functional task training, musculoskeletal intervention (passive) and neurophysiological intervention Length of intervention period: not stated Number of sessions and length of individual sessions: not stated Intervention provider: not stated (3) Control group (n = 30) "another 30 persons in internal neurology department were selected as the control group with pharmacy treatment alone" "No rehabilitation exercise or intermediate frequency therapy were administered in con- trol group" The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising no intervention Length of intervention period: no intervention Number of sessions and length of individual sessions: no intervention Intervention provider: no intervention Number of sessions and length of individual sessions: no intervention Intervention provider: no intervention This study is classified as intervention (functional task training, musculoskeletal (passive) , neurophysiological) versus no treatment (Table 4). The intervention group also received assistive devices
Outcomes	Measures of motor function: Fugl-Meyer Assessment Time points when outcomes were assessed: "the patients in three groups were evaluated at the beginning, 2 weeks, 4 weeks and 8 weeks after therapy and the patients in control group were evaluated in their family"
Notes	Short Chinese study published in English Not clear how the dose varied between groups (1) and (2): both groups used for analysis, with control group 'shared' between Mean and SD computed from categorical data

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	High risk	Not stated "among them, randomly selected 30 per- sons as the rehabilitation group, and an- other 30 randomly selected persons were grouped into rehabilitation with interme-

		diate frequency" Unclear how the control group was se- lected: "another 30 persons in internal neu- rology department were selected as the con- trol group with pharmacy treatment alone"
Allocation concealment (selection bias)	Unclear risk	No information provided
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	No information provided
Incomplete outcome data (attrition bias) All outcomes	Unclear risk	No dropouts described
Free of systematic differences in baseline characteristics of groups compared?	Low risk	Limited information available regarding the baseline characteristics. Gender and age are similar in the rehabilitation groups but there is a potential gender bias in the con- trol group. However, baseline Fugl-Meyer scores are similar across all groups
Did authors adjust for baseline differences in their analyses?	Low risk	No information provided
Other bias	Unclear risk	No information provided

Zhang 1998

Methods	Study design: RCT Method of randomisation: not stated ("participants were randomly allocated to 2 groups")
Participants	Number of participants: n = 56 Inclusion criteria: "patients were diagnosed using clinical appearance and cerebral CT as having cerebro-vascular disease"
Interventions	 (1) Early rehabilitation group (n = 29) "The intervention groupunderwent early rehabilitation therapy in conjunction with normal medical therapy" "Stage 1 (lying exercises): The patient is without any independent movement, and is in a state of flaccid hemiplegia. The patient is placed in a functional position and lightly massaged on the hands and limbs. Limbs are passively extended and retracted in small and large movements. This is in addition to rolling the patient on the bed and single and double leg bridge movements. The goal is to gradually lead the patient to balancing the trunk in a sitting position" "Stage 2 (sitting exercises): When the patient gains some muscle strength and muscle groups can react and work in groups, continue the exercises described above until the

	goals in stage one are achieved. In the meantime, add balancing exercises as well as resistance training in the sitting position. At the same time, stimulate sensory input by using cold and hot compresses and light taps to the antagonistic muscles. Gradually lead the patient into training for balancing while standing up" "Stage 3 (standing exercises): When the patient is at the stage where his limbs spasm and can freely initiate movement in groups, continue the exercises in stage 2 until goals are met as well as correcting and controlling irregular positions and increasing normal movement and co-ordination. In order to prepare for walking, exercise the extensor carpi muscles, supination of forearm, standing with support, standing with weights on the lower limbs and walking with support" "Stage 4 (walking exercises): when the patient's spasming eases, continue to complete the goals set out in stage 3 as well as walking indoors and on stairs, correcting walking posture, co-ordination and completing ADL activities" "Patients about to be discharged from hospital were also trained to perform ADL. For individuals with slow recovery of function, we encouraged them to overcome dependence on others and actively participate in social activities. For some patients, it was necessary to advise occupational training" "Psychological therapy: Patients with depression, pessimism, loss of confidence and un-willingness to cooperate with therapy were promptly given psychological care, allowing the patient to rehabilitation is essential" The individual components delivered are listed in Table 3. Based on the individual components, this intervention scategorised as comprising functional task training, musculoskeletal intervention [20, Control group (n = 27) "underwent conventional neurological medical therapy" The individual components delivered are listed in Table 3. Based on the individual components, theil intervention is categorised as comprising no intervention Length of individual sessions: "Therapy was conducted with the h
Outcomes	Measures of independence in ADL: Barthel Index Measures of motor function: Fugl-Meyer Assessment Other secondary outcome measures: "recovery of mobility was assessed according to the Brunnstrom 6 classification" Time points when outcomes were assessed: "assessments of all patients' condition[s] were conducted 3 months after onset of symptoms"

Zhang 2004

Methods	Study design: RCT Method of randomisation: not stated
Participants	Number of participants: n = 1078 Inclusion criteria: "Ischaemic or haemorrhagic stroke, confirmed by CT or MRI scan, satisfied the Fourth National Conference on Cerebral Vascular Disease classification guidelines, first ever stroke, aged below 85 years old, Glasgow Coma Scale > 8 and deficits in limb function" Exclusion criteria: "Subarachnoid haemorrhage and transient ischaemic attack, aggrava- tion of medical condition or progressing ischaemia or haemorrhage and impaired func- tion of the heart, lungs, liver, kidney and other vital organs etc"
Interventions	(1) Rehabilitation group (n = 439) "Building a tertiary rehabilitation network: Establish a tertiary rehabilitation network (3- tier medical, rehabilitation network) from several hospitals' Department of Neurology- rehabilitation centres (or merge hospitals' Department of Rehabilitation)-community rehabilitation organisations (or home therapy) from several cities in the whole country Patients from the rehabilitation group first stayed at the hospital's Department of Neu- rology, receiving 28 days of critical phase routine medical care and early rehabilitation.

Based on ADL ability, patients who were ADL independent, who discharged to home, transferred to community rehabilitation organisations to undertake their rehabilitative training, to further improve their exercise ability, integration ability and ADL ability. Patients who were unable to reach ADL independence or still had moderate to severe functional disability after the early rehabilitation period, were transferred to rehabilitation centres or the tertiary rehabilitation network hospitals' Department of Rehabilitation to undertake specific strengthening training, to minimise the patient's functional disability. This phase usually took approximately 2 months. After which, patients transferred to community rehabilitation organisations to undertake further rehabilitative training, to consolidate effects from previous rehabilitation, and to continue rehabilitation for other persisting functional disabilities. Patients in the control group discharged home after 28 days of routine treatment and early rehabilitation, were given pre-arranged guidance from professionals, and undertook rehabilitative training on their own or with assistance from their family. Community rehabilitation in certain regions was not developed, were unable to provide community rehabilitation, thus patients had to return to the tertiary rehabilitation network Department of Rehabilitation to continue training. Each tertiary rehabilitation network utilised uniform inclusion criteria to select patients, with randomisation to the rehabilitation or control group. Personnel involved in the tertiary rehabilitation network included doctors, therapists, assessors who undertook training sessions to ensure uniformity at all centres. All tertiary rehabilitation network centres used a uniform rehabilitation training method and outcome assessment"

"Tertiary rehabilitation network treatment: Treatment during the critical phase was guided by Zhonghua Medical Association's recommendations. Rehabilitative training focused on physiotherapy (PT) and occupational therapy (OT), with speech and language therapy and psychological therapy given at centres with the capabilities. Physiotherapists delivered therapy uniformly, using Bobath techniques and methods from the motor relearning program mainly, with added use of PNF techniques, Brunnstrom etc. Therapy and training followed the patient's stroke recovery characteristics, adjusting to the patient's actual functional status, and delivered systematically and progressively"

"Training content: During the period when patient was confined in bed, passive ranging, optimal limb positioning, rolling, sitting up, bridging exercises in bed, sitting on bed, sitting balance training etc was given. When patient could achieve sitting for 30 min without postural hypotension or other symptoms, the patient could use a wheelchair to undertake training in the gym. Training content mainly included: active-passive exercises, standing and standing balance training, lower limb weight training and shifting of centre of mass training, stepping practice and gait correction, ankle dorsiflexion, fore-arm pronation and supination, finger grasping etc. Family members were taught rehabilitative training methods, and at the same time, patient and family underwent health counselling, given a health education booklet, shown a video on neurological recovery etc, with the aim of furthering the patient's recovery"

The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising functional task training, musculoskeletal intervention (active), musculoskeletal intervention (passive) and neurophysiological intervention

Length of intervention period: six months

Number of sessions and length of individual sessions: dependent on stage of recovery (see above)

Intervention provider: doctors and therapists

Zhang 2004 (Continued)

	 (2) Control group (n = 463) "The control group received conventional neurological medical therapy only. Patients in the control group discharged home after 28 days of routine treatment and early rehabilitation, were given pre-arranged guidance from professionals, and undertook rehabilitative training on their own or with assistance from their family" The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising no intervention Length of intervention period: six months Number of sessions and length of individual sessions: no intervention Intervention provider: no intervention This study is classified as intervention (functional task training, musculoskeletal (active), musculoskeletal (passive), neurophysiological) versus no treatment (Table 4)
Outcomes	Measures of independence in ADL: Barthel Index Measures of motor function: Fugl-Meyer Assessment Measures of tone or spasticity: Ashworth Scale Measures of quality of life and social isolation: SF-36 Other secondary outcome measures: Loewenstein Occupational Therapy Cognitive As- sessment (LOTCA), NIHSS, WAB (speech assessment), Hamilton (depression assess- ment) Time points when outcomes were assessed: within one week after stroke and at the end of each month for six months

Zhu 2001

Methods	Study design: RCT Method of randomisation: not stated
Participants	Number of participants: n = 125 Inclusion criteria: "Satisfied the 1995 Fourth National Conference on Cerebral Vascular Disease classification guidelines, confirmed by CT or MRI scan as first ever stroke; Functional deficit of limbs; Aged between 45-70 years old, no major heart, liver, kidney and other organ diseases; Glasgow Coma Scale \geq 8 within 4-7 days for ischaemic stroke, within 10-14 days for haemorrhagic stroke, vital signs stable"
Interventions	 (1) Rehabilitation group (n = 72) "Both groups received conventional medical treatment during the critical acute phase. Participants in the treatment group commenced rehabilitation once medically stable. Rehabilitation comprised exercise therapy, occupational therapy and electro therapy etc. Exercise therapy consisted of techniques mainly from the Motor Relearning Program and Bobath, customised to the impairment of the individual participants and progressed appropriately. Exercise therapy included: (i) Passive ranging exercises of all joints of the affected limbs (including scapula), starting from small to large movements, without any pain caused to the participants; (ii) Rolling practice to both sides; (iii) bridging exercises; (iv) Exercises involving the wrist and ankle joints; (v) outwith therapy, participants trained in upright sitting, beginning at an inclination angle of 30 degrees. Once participants could tolerate the angle for 30 min, the inclination was increased by 10 degrees until participants could sit upright at 90 degrees for 30mins. Thereafter, participants commenced sitting on the edge of bed exercises and lying to sitting training; (ix) gait training etc. Throughout therapy, participants' family were taught the exercises, so that they could assist with practice outwith therapy. Electrotherapy was conducted for the affected limbs. Psychological therapy was given throughout to strengthen participant's motivation to recover" "Although the control group was not given any therapy, some participants exercises based on the doctor's advice, and some participants from the treatment group continued with outpatient therapy or home therapy or assistance with daily exercises by their family under telephone supervision at least 3/week" The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising functional task training, modality, musculoskeletal intervention (passive) and neurophysiological

Allocation concealment (selection bias)	Unclear risk	No information provided
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Blinded assessment
Incomplete outcome data (attrition bias) All outcomes	Unclear risk	No dropouts described
Free of systematic differences in baseline characteristics of groups compared?	Low risk	No statistically significant differences in baseline values
Did authors adjust for baseline differences in their analyses?	Low risk	No information provided
Other bias	Unclear risk	No information provided

Zhu 2006

Methods	Study design: RCT Method of randomisation: "Randomised according to the time of hospital admission"
Participants	Number of participants: n = 70 Inclusion criteria: "Ischaemic or haemorrhagic stroke, confirmed by CT or MRI scan as first ever stroke, aged between 55-80 years old, functional deficit of limbs, no severe

cognitive issues, no severe diseases of the heart liver, kidney and other organs, within 1 week of being medically stable and Glasgow Coma Scale > 8"
 (1) Test group (n = 35) "Both groups of patients received the same drug therapy, including treatment for cerebral defma, brain care and improving blood circulation. 3 - 7 days after becoming medically stable, the test group underwent rehabilitative therapy using Bobath technique, Rood technique, as well as ADL training, etc, with training conducted by rehabilitation nurses, rehabilitative therapy once a day, 1 hr each time, 5 times a week" "The contents were as follows: Physiotherapy: (i) On-bed positioning of healthy limbs, with regular turning over; (ii) Passive ranging exercises of joints of limbs on affected side, including passive ranging exercises of scapular, motion progressing from proximal joints to distal joints, range of motion progressed from small to large, within pain-free thresholds, while concurrenty, patients were encouraged to use healthy limbs to aid motion of affected limbs, for example exercise involving crossing both sides and lifting, lower limbs bridge-style exercise; (iii) Utilising Rood technique to brush, tap, pat et carbitrary exercises to stimulate affected limbs; (iv) Sitting exercise involving lifting headrest, headrest gradually lifted, maintaining and thealty training of maintaining obtand-forth, side-to-side and rotation training, and finally training of maintaining balance while being pushed externally; (vi) Sit-to-stand balance training, torso back-and-forth, side-to-side, (vii) Sit-to-stand balance training, form gait training body weight back-and-forth, side-to-side; (vii) Gait training of moving body weight back-and-forth, side-to-side; (vii) Gait training of maintaining balance and affected limbs weight bearing ability improved, starting from gait training balance and affected limbs using walking stick and eventually progressing to training of star climbing and descending" "Occupational therapy: (i) For patients with difficulty swallowing, training was done to stimulate face, tongue and lips, opening and closing of lips, openin

Zhu 2006 (Continued)

	The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising no intervention Length of intervention period: no intervention Number of sessions and length of individual sessions: no intervention Intervention provider: no intervention This study is classified as intervention (functional task training, musculoskeletal (passive) , neurophysiological) versus no treatment (Table 4)
Outcomes	Measures of independence in ADL: Modified Barthel Index Measures of motor function: Fugl-Meyer Assessment (simplified) Other secondary outcome measures: Brunnstrom Grading Scale Time points when outcomes were assessed: before and after intervention
Notes	Original study translated from Chinese to English

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	High risk	"Randomised according to the time of hos- pital admission"
Allocation concealment (selection bias)	High risk	"Randomised according to the time of hos- pital admission"
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	No information provided
Incomplete outcome data (attrition bias) All outcomes	Unclear risk	No dropouts described
Free of systematic differences in baseline characteristics of groups compared?	Low risk	No statistically significant differences in baseline values
Did authors adjust for baseline differences in their analyses?	Low risk	No information provided
Other bias	Unclear risk	No information provided

Zhu 2007 haem

Methods	Study design: RCT Method of randomisation: "Stratified block randomisation"
Participants	Number of participants: n = 78 Inclusion criteria: "Provided informed consent, medically stable for > 48hours, Glasgow Coma Scale > 8 and functional deficit of limbs"

	Exclusion criteria: "Active liver disease, impaired liver, kidney function, congestive heart failure, impaired respiratory system, malignant tumours, history of dementia, history of psychological disorders, paralysis of 4 limbs, more than 4 weeks post stroke, history of previous stroke which resulted in functional deficit of limbs, unable to allow reassessments to take place and deafness and/or muteness"
Interventions	 (1) Cerebral haemorrhage rehabilitation group (n = 12) "All patients received routine clinical treatment and care. Treatment group was transferred to rehabilitation centre after becoming medically stable, and under guidance from the therapists, utilised physiotherapy and occupational therapy to undergo integrated rehabilitative treatment; patients on being discharged to their homes, were visited by therapists who would teach the required training, until the follow-up ended" "Key training contents included: (i) From 1 week after medical stabilisation till one month after onset of stroke, focus was on bed and bed-side exercises, including antispasticity positioning, passive exercises on affected limbs, truncal muscle control training, shifting on bed, rolling (affected side, non-affected side), sitting up, sitting-balance training, sitting position-standing position transfer as well as eating, grooming, dressing etc ADL training, once a day, 45 min each time, 5 days a week. (ii) From start of 2nd month ill end of 3rd month after onset of stroke, focus was on standing training, including standing-balance training, single-leg weight bearing, gait and stair climbing/descending, and other trainings, while providing guidance on tolleting, bed-chair transferring, indoors or outdoors walking, use of stairs, washing and other practical ADLs; twice a day, 45 min each time, 5 days a week. Because muscle tone could increase gradually during this period, it was necessary to increase the intensity of training to reduce muscle tone and inhibit abnormal exercise patterns. For some patients who returned to community setting, therapists would conduct weekly home-visits to guide the patient on rehabilitative treatment. (iii) Once training had commenced, therapists concurrently raught the patients' family members or caregiver on the correct asistive training methods and care methods, such that they could provide some training functional task training and musculoskeletal intervention (passive) Len

Zhuang 2012

Methods	Study design: "RCT with 3 treatment groups" Method of randomisation: "Research team randomly assigned participants to one of three groups: (1) acupuncture alone, (2) physiotherapy alone, or (3) combined acupuncture and physiotherapy. The team's data management center generated the randomization numbers with SAS9.1.3 (Statistical Analysis System provided by SAS Institute Inc, Cary, North Carolina). Each of the seven sites had a designated research assistant who was responsible for obtaining a random number for each participant from a web-based, password-protected Internet site and who actually assigned the participant to one of the three treatment groups"
Participants	Number of participants: n = 274 Inclusion criteria: recent (longer than two weeks and less than three months) history of ischaemic stroke that clinical signs and imaging confirmed, admission to a specialist stroke unit as an inpatient, participants of either sex, age from 45 to 70 years, ability to give informed consent, participants also had to "score better than 10 on the Neurologic Defect Scale (NDS), which ranges from 0 to 45, with 45 as most severe"

	Exclusion criteria: haemorrhagic cerebrovascular disease, vascular disease and dysfunc- tion, history of dementia or other mental illness, cancer, diseases transmissible by blood, severe disease of the heart, liver, kidney, hematopoietic system or endocrine system, se- vere visual or hearing impairment, history of previous acupuncture, fear of needling
Interventions	 (1) Physiotherapy (n = 86) "The research team based the physiotherapy, a conventional rehabilitative method for stroke, on the Bobath approach, which intends to restore normal movement and improve muscle strength" The individual components delivered are listed in Table 3. Based on the individual components, this intervention is categorised as comprising neurophysiological intervention Length of intervention period: four weeks Number of sessions and length of individual sessions: "six 60-minute sessions per week of standard physiotherapy and six 45-minute sessions per week of occupational therapy". Intervention provider: "qualified therapists. A physiotherapist tailored the treatment protocol to each participant's needs, based on recovery stage" (2) Acupuncture (n = 91) "All participants received conventional care as needed, including psychological counselling, standard nursing care, and daily medical evaluation. Attending physicians, blinded to the participant's treatment assignment, prescribed medications when appropriate, including drugs for controlling blood glucose concentration, blood lipid levels, and blood pressure. The study allowed antiplatelet agents and anticoagulants at the discretion of the attending physician" "Well-trained, qualified, experienced acupuncturists performed the acupuncture treatments, with participants in the supine position. The acupuncturist used sterile, disposable needles: 30-gauge (0.3 mm in diameter), 40-mm-long needles for limb points and 32-gauge (0.25 mm in diameter), 25-mm-long needles for limb points and acupuncture textbook for the depth and angle of insertion into each acupuncturist selected secondary acupoints based on traditional Chinese medicine (TCM) theory. Patients with flacid paralysis received Quebi (L111), Waiguan (TES), and <i>Hegu</i> (L14) for the upper limb and <i>Yinlingguan</i> (SP9) and <i>Sanyinjiao</i> (SP6) for the lower limb." The individual components delivered are listed in Table 3. Based on

Physical rehabilitation approaches for the recovery of function and mobility following stroke (Review) Copyright © 2014 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

Zhuang 2012 (Continued)

	during the same half-day" The individual components delivered are listed in Table 3. Based on the individual com- ponents, this intervention is categorised as comprising modality and neurophysiological intervention Length of intervention period: four weeks Number of sessions and length of individual sessions: "participants received treatments once a day except on Sundays" Intervention provider: "qualified therapists" This study is classified as active Intervention one (neurophysiological) versus active in- tervention two (acupuncture) (Table 6)
Outcomes	Measures of independence in ADL scales: Modified Barthel Index Measures of motor function: Fugl-Meyer Assessment Other secondary outcome measures: Neurologic Defect Scale (NDS) Time points when outcomes were assessed: "research team evaluated all patients at base- line, after 2 weeks, and after 4 weeks"
Notes	For analysis, we have just used Groups (1) and (2). As Group 2 did not receive any active physical rehabilitation in addition to acupuncture, we will explore the categorisation of this group with sensitivity analysis

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	"The team's data management center gen- erated the randomization numbers with SAS9.1.3 (Statistical Analysis System pro- vided by SAS Institute Inc, Cary, North Carolina). Each of the seven sites had a des- ignated research assistant who was respon- sible for obtaining a random number for each participant from a web-based, pass- word-protected Internet site and who actu- ally assigned the participant to one of the three treatment groups"
Allocation concealment (selection bias)	Low risk	"research assistant instructed participants not to discuss other treatments that they were receiving with their therapists"
Blinding of outcome assessment (detection bias) All outcomes	Low risk	"Physicians who performed the outcome assessments were blinded to treatment as- signments. The principal investigator was blinded to treatment assignment and was not involved in treating the patients"

Zhuang 2012	(Continued)
2000	(00////////////////////////////////////

Incomplete outcome data (attrition bias) All outcomes	Low risk	Dropouts accounted for "Of those who dropped out, nine left the hospital, eight discontinued treatment, two dropped out due to poor health, one (from the acupuncture group) suffered a second stoke and one (from the physiotherapy group) died due to a respiratory tract infec- tion"
Free of systematic differences in baseline characteristics of groups compared?	Low risk	"At baseline, no significant differences ex- isted between the three groups in terms of gender, age, or length or severity of disease (P > 0.05)"
Did authors adjust for baseline differences in their analyses?	Low risk	No information provided
Other bias	Unclear risk	"Due to the lack of a sham-acupuncture, placebo-control group, the research team cannot rule out the possible placebo effect of acupuncture"

ADL: activities of daily living.
AEP: additional early physiotherapy.
BI: Barthel Index.
BPM: balance performance monitor.
CG: control group.
CNDS: Clinical Neurological Deficit Scale.

Characteristics of excluded studies [ordered by study ID]

Study	Reason for exclusion
Acalha 2010	Design: unclear. ("Thirteen chronic stroke patients were divided into experimental group-EG ($n = 7$) and control group-CG ($n = 6$).") Abstract only. Clarification of randomisation and intervention sought but not obtained
de Paula Oliveira 2007	Design: RCT. Abstract only. Clarification of intervention sought but not obtained. Study excluded because of insufficient information available regarding intervention
Dean 2000a	Repeated case study (n = 3); confirmed by correspondence with the author
Dickstein 1986	Cohort design, not RCT: quasi-randomisation of participants (based on administrative procedures) to one of 13 physiotherapists; however, each physiotherapist provided treatment interventions in a predetermined (not randomised) order (first five participants received treatment A, next five participants treatment B, next five participants treatment C); this study was therefore assessed to be a cohort design rather than a randomised trial
Eng 2003	Repeated measures design; not RCT
English 2003	Alternating allocation, not RCT: "Patients admitted into a stroke unit during particular time periods were allocated to either arm of the trial, e.g. weeks 1 to 6 to treatment group, weeks 7 to 12 to usual care and so on"
Gong 2003	Design: unclear (further information required). Clarification of randomisation sought but not obtained
Gregson 2003	Design: single-centre, single-blind RCT. Clinical trial protocol only available. Results presented at a confer- ence in July 2005. No publication intended as of 22 November 2011. Clarification of intervention sought but not obtained. Study excluded because of insufficient information regarding intervention
Hesse 1998	Single-participant design
Inaba 1973	Compared three orthopaedic approaches; excluded from this version of the review; quasi-randomisation
Karaduman 2001	Study not randomised (confirmed by correspondence with study author)
Khanna 2003	This study was never carried out (confirmed by correspondence with study author)
Kim 2001	Specific strength training intervention (i.e. component, not approach)
Krutulyte 2003	Design: unclear (further information required). Clarification of randomisation sought but not obtained
Li 2004	Trial of a specific balance training intervention (i.e. component, not approach)
Lin 2004	Trial of timing of intervention (i.e. component, not approach)
Liu 2008	Quasi-randomised study

(Continued)

Meng 2005	Design: unclear (further information required). Clarification of randomisation sought but not obtained
Ng 2005	Design: unclear (further information required). Clarification of randomisation sought but not obtained
Nissan-Lavi 2009	British Library unable to locate or supply the document. We were also unable to contact the study author to obtain a copy of the paper
Ozdemir 2001	Quasi-randomised study
Pomeroy 2001a	This study was never carried out (confirmed by correspondence with study author)
Pyoria 2007	Controlled clinical trial, not a randomised controlled trial
Qiu 2004	Trial of a specific balance training intervention (i.e. component, not approach)
Richards 2004	Compares two different intensities of a mixed approach
Salter 1991	Collected data retrospectively from participant charts; had not used preplanned data collection
Stern 1970	Quasi-randomised study
Stuart 2008	Non-randomised controlled study
Thielman 2004	Treatment intervention and outcomes concentrated on upper limb
Wagenaar 1990	Compared two neurophysiological approaches; excluded from this version of the review; quasi-randomisa- tion
Wang 2005b	Study not randomised ("Total of 100 patients with CVA were selected and divided into test and control group, 50 cases each")
Wolny 2003	Study not randomised ("Two 20-subject groups-the experimental one and the control one, participated")
Wood 1994	Study never carried out (confirmed by communication with study author)
Xu 2008	Design: RCT Abstract only available. Further details sought regarding the intervention but not obtained. Study excluded because of insufficient information available regarding intervention
Yin 2003b	Study not randomised
Yu 2008	Design: RCT Abstract only available. Further details sought regarding the intervention but not obtained. Study excluded because of insufficient information available regarding intervention
Zhong 2006	Design: unclear (further information required). Clarification of randomisation sought but not obtained

(Continued)

Zhou 2003	Study not randomised ("Patients were divided into treatment group $(n = 50)$ and control group $(n = 50)$.")
Zhu 2004a	Quasi-randomised study

n: number of participants.

RCT: randomised controlled trial.

Characteristics of studies awaiting assessment [ordered by study ID]

Giraux	2008

Methods	Design: multi-centre RCT
Participants	Estimated enrolment: n = 240 Inclusion criteria: "(1) Patients must be aged between 18 to 75 years, with a first ischemic or hemorrhagic stroke at least six months ago and no longer than two years ago, without a subsequent stroke. It must have caused initially complete hemiplegia of the right or left hemibody, but they must be able [to] walk alone with or without technical assistance over a distance of at least 10m. They must be able to change direction too and (2) They must have a functional ambulation classification score between 4 and 6 during the inclusion" Exclusion criteria: "(1) We will exclude patients with a neurological history other than a stroke, a psychiatric illness, or an associated debilitating disease, (2) They must not have an associated cerebella syndrome or a clinical brainstem attack and (3) We will refuse patients who are pregnant, who have not signed the written consent and who aren't entitled to a social security scheme"
Interventions	"(1) Active comparator: patients who continue physical therapy sessions during two months. Intervention: be- havioural-two physical therapy sessions per week for two months" "(2) No intervention: patients who stop physical therapy sessions during two months. Intervention: behavioural- patients who stop two physical therapy sessions per week for two months"
Outcomes	Primary outcome measures: average number of steps/d recorded over three days in an outpatient setting. To be measured at day three and then six months later Secondary outcome measures: Six-Minute Walking test, Wade's test, Rivermead Mobility Index score and Barthel Index. These will be measured at day zero and at day 55
Notes	Clarification of intervention sought but not obtained
Li 2000	
Methods	Design: "prospective RCT"
Participants	"The interview group was targeted from 200 stroke patients who participated and were discharged from the prospective randomised controlled trial between 1995 to 1997. All cases were confirmed to be first onset by clinical and CT or

Physical rehabilitation approaches for the recovery of function and mobility following stroke (Review) Copyright © 2014 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

MRI diagnosis. This did not include less severe or very severe cases"

Li 2000 (Continued)

Interventions	"The control group (n = 100) only received conventional neurological treatment, while the rehabilitation group underwent an early rehabilitation program commencing on an average of 9 days after diagnosis with bedside exercises, in addition to the treatment"
Outcomes	"The interview was conducted in the form of calls and letters, with the time of interview being 18 months after treatment. The interview content included the patient's survival, functional mobility, environment patient was mobile in, ADL ability, quality of life (QOL) and any secondary injury. The latter included joint pain, joint range of motion, limb or hand swelling, muscle atrophy, pressure ulcers, lung and urinary tract infection, with 1 point given for presence of secondary injury and no points for the absence of injury"
Notes	Original study translated from Chinese to English. This study is a follow-up from an earlier study undertaken in 1998. British Library unable to supply this earlier publication, and, despite extensive searching, the reviewers have not been able to find any other known UK locations for it. Clarification of intervention from the earlier RCT was sought from the study authors but was not obtained

Matsumoto 2010

Methods	Design: single-blind, parallel RCT
Participants	Target sample size: n = 50 Inclusion criteria: (1) between 20 and 80 years old, (2) post-stroke patients whose onset was between one and six months Exclusion criteria: (1) severe higher brain dysfunction, (2) severe dementia and (3) loss of consciousness
Interventions	Trunk facilitation technique and without trunk facilitation technique. No further details available
Outcomes	Primary outcomes: muscle strength, Functional Assessment for Control Trunk, Berg Balance Scale, Functional Reach Test, 10-Metre Gait Measurement, Functional Independence Measure
Notes	Clarification of intervention sought but not obtained

Richardson 2011

Methods	Design: single-blinded randomised controlled trial
Participants	Delivered to persons with stroke +/- 18 years, community dwelling and able to walk 100 metres independently. Still recruiting participants Inclusion criteria: (1) adults > 18 years, (2) living in the community, (3) able to ambulate > 10 metres with or without an assistive device, (4) able to tolerate 60 minutes of activity with rest intervals, (5) have clearance from a physician to participate in the programme, (6) can independently follow instructions and (7) are not involved in active rehabilitation Exclusion criteria: (1) musculoskeletal contraindications to exercise, (2) unstable cardiovascular conditions, (3) unstable medical conditions and (4) significant cognitive impairment
Interventions	"12 week intervention comprised of group and individual exercise programs and an 8 week, Living with Stroke Education program (1 hr/week). The intervention was delivered by kinesiologists (YMCA) with consultation from physiotherapists (Hamilton Health Sciences)"

Richardson 2011 (Continued)

Outcomes	Primary outcomes: Six-Minute Walk Test (6MWT), Hand Grip Strength and Rapid Assessment of Physical Activity Secondary outcomes: Patient Activation Measure Participants were assessed at baseline, 12 weeks and 24 weeks by a blind assessor
Notes	Clarification of intervention sought but not obtained Further details about the trial are available at www.clinicaltrials.gov (NCT01194102)

Sanchez-Sanchez 2011

Methods	Design: randomised double-blind controlled trial				
Participants	"25 patients (mean age 77.20 ± 7.SS) were included in the study and 11 completed the protocol (control group n = 4, target group n = 7)" Inclusion criteria: "Patients over 60 years old who had suffered a single stroke episode with residual hemiparesis, ability to walk before stroke and to be clinically stable enough to begin physiotherapy" Exclusion criteria: "Blindness, prosthetics or significant osteoarthritis of the lower limbs, serious cardiac disease and severe cognitive impairment"				
Interventions	"Control and target groups were treated with conventional physiotherapy for stroke, but we added specific techniques to the target group depending on patient's functional level"				
Outcomes	"Outcome measures were balance on Berg Balance Scale: walking ability on gait speed and HS Functional Ambulation Classification (FACHS), and functional ability on Barthel Index. Assessment was done at baseline, on the fourth and the twelfth week"				
Notes	Abstract only. Clarification of intervention sought but not obtained				

Wang 2005a

Methods	Design: unclear ("were divided randomly into rehabilitation group and control group"). Both groups received norma treatment and general nursing, based on which rehabilitation group received rehabilitation training					
Participants	"62 post-stroke hemiplegic patients"					
Interventions	"Both groups received normal treatment and general nursing, based on which rehabilitation group received rehabil- itation training. The therapy of movement was divided into four stages, which included posture in lying training, eating training, standing training and walking training. We designed several examination methods in activity of daily life such as beating ball, picking up beans, stirring abacus, taking off clothes, using dishware, etc"					
Outcomes	"Six-period opinion method and Modified Bathel Index were used to evaluate motor function of limbs and activity of daily life in the first week of hospitalization and before discharge"					
Notes	British Library unable to supply this publication, and, despite extensive searching, the review authors have not been able to find any other known UK locations for it. Clarification of intervention was sought from the study authors but was not obtained					

Wang 2012						
Methods	Design: unclear ("A multi-center intervention study was conducted in five sub-centers of three cities in China. V randomly evaluated the awareness of rehabilitation and situation of receiving rehabilitation services in the stro survivors")					
Participants	"Three hundred and forty-two patients successfully completed three-month rehabilitation training in the community health neighbourhood service center"					
Interventions	"The intervention measures comprised a rehabilitation information package and a new rehabilitation exercise program that is a simplified form of Conductive Education"					
Outcomes	"We used the Fugl-Meyer Assessment (FM) to evaluate motor function, and Barthel index (BI) to evaluate activitie of daily living (ADL)"					
Notes	Abstract only. Clarification of randomisation and intervention sought but not obtained					
Yau 2010						
Methods	Design: randomised double-blinded controlled trial					
Participants	"Thirty-nine (21 male, 18 female) stroke patients with mild mobility limitation, were recruited within one-week of onset and randomized to augmented therapy group (ATG) or control group (CG)"					

Interventions	"Subjects from both groups received additional exercise sessions for three days. Exercise program for ATG was based on task-oriented strength training of the lower limb while those for the CG contained dexterity exercises within arm- reach"
Outcomes	Outcome measures included modified functional ambulation classification, modified Rivermead Mobility Index, functional reach, five times sit to stand, step test, Berg Balance Scale (BBS), Timed Up and Go test and gait speed (comfortable and maximum) were performed at recruitment and after intervention Participant compliance and any adverse events were also recorded
Notes	Abstract only. Clarification of physical therapy intervention was sought but was not obtained

Zhang	2008
-------	------

Methods	Design: unclear ("divided randomly into 2 groups: the treatment group and the control group")			
Participants	"80 cases with acute brain vascular disease"			
Interventions	"The treatment group was treated with three grades regular rehabilitation treatment whereas the control received no rehabilitation treatment unless treated with acupuncture or massage by patients themselves. Both groups received routine treatment of internal medicine"			
Outcomes	"Both groups were evaluated with simplified Fugl-[Meyer] (FM) scale at the beginning and the end of the treatment"			
Notes	Abstract only. Clarification of intervention sought but not obtained			

Characteristics of ongoing studies [ordered by study ID]

Cross 2009

Trial name or title	The FeSTivaLS trial protocol: a randomised evaluation of the efficacy of functional strength training on
	enhancing walking and upper limb function later post stroke
Methods	Randomised, observer-blind trial with embedded qualitative investigation of participants' views of functional strength training
Participants	"Participants (n = 58), six months to five years after stroke with difficulty using their paretic upper and lower limbs for everyday functional activity"
Interventions	"All will be randomized to either: (1) functional strength training-upper limb or (2) functional strength training-lower limb delivered in their own homes for fours days each week for six weeks. FST involves repetitive progressive resisted exercise during goal directed functional activities. The therapist's main input is to provide verbal prompting and feedback"
Outcomes	"Measures will be undertaken before randomization (baseline), after the six-week intervention (outcome) and six weeks thereafter (follow-up). Primary outcomes for clinical efficacy will be the Functional Ambulation Categories (FAC) and the Action Research Arm Test (ARAT)"
Starting date	Unclear
Contact information	Dr Kathryn Mares, School of Allied Health Professions, University of East Anglia, Queen's Building, Norwich Research Park, Norwich, NR4 7TJ, UK E-mail: k.mares@uea.ac.uk
Notes	The trial is registered on the Current Controlled Trials database (ISRCTN71632550). The full protocol has also been published (see Mares et al (2013) (Cross 2009))

Kumaran 2010

Trial name or title	Effectiveness and feasibility of a task and context-based exercise programme in stroke patients: a randomised controlled trial
Methods	Randomised, parallel-group, active-controlled trial
Participants	"Total sample size = 202; sample size from India = 202" Inclusion criteria: "(1) first stroke discharged from hospital; (2) ischemic stroke (3) aged between 30 years and 65 years; (4) both sexes; (5) a minimum of three months post stroke duration; (6) the ability to ambulate at least 5 meters with supervision or guarding; (7) the ability to understand instructions and follow simple commands" Exclusion criteria: "(1) patient with a present history of severe, uncontrolled, or unstable cardiac disease; (2) other systemic disorders for which exercise is contraindicated; (3) terminally ill; (4) hearing and visually challenged; (5) any other coexisting conditions that would interfere with outcome assessments or participation in treatment regimens"
Interventions	"Randomized controlled trial evaluating the effectiveness and feasibility of a task and context based exercise program in stroke patients. patients in control will receive conventional physiotherapy exercises whereas

Kumaran 2010 (Continued)

	patients in experimental group will receive task and context based exercise program. both the group will receive exercise program thrice weekly, for a period of 12 weeks. primary outcome measure is stroke impact scale score"
Outcomes	Primary outcome measures: Stroke Impact Scale score Secondary outcome measures: Motricity Index score, gait velocity by 5-Metre Timed Walk test, Berg Balance Scale score, walking distance by Six-Minute Walk test, impact on participation and autonomy questionnaire score, falls efficacy scale-international score Time points: pre eight weeks, post eight weeks, post 12 weeks, post 16 weeks
Starting date	Registered on 27 April 2010; date of first enrolment 16 August 2011
Contact information	Senthil Kumaran, Associate Professor, Department of Physiotherapy, MCOAHS, Manipal University, Udupi, Karnataka 576104, India E-mail:senthil.kumaran@manipal.edu
Notes	CTRI/2010/091/000278

DATA AND ANALYSES

Comparison 1. Intervention versus no treatment: immediate outcomes

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size

ADDITIONAL TABLES

Table 1. Criteria for classification of neurophysiological and motor learning approaches

Name of approach	Philosophy/theory	Treatment principles	Descriptive terms	Supporting references
Rood (neurophysiological)	teraction of somatic, au-	Activate/facilitate move- ment and postural re- sponses of patient in	Developmental	Goff 1969; Rood 1954; Stockmeyer 1967
	factors, and their role in regulations of motor be- haviour'. Motor and sensory func- tions inseparable Focuses on the develop-	same automatic way as they occur in the normal Sequenc- ing of movement from basic to complex (supine lying; rolling; prone ly- ing; kneeling; standing; walking)	Postural stability Normal patterns of movement Joint and cutaneous re- ceptors Golgi tendon organs	

Proprioceptive neuromuscular facilitation (PNF) or Knott and Voss (neurophysiological)	Active muscle contrac- tions intended to stimu- late afferent propriocep- tive discharges into the CNS increased excita- tion and recruitment of additional motor units Assumes that central and peripheral stimu- lation are enhanced and facilitated in order to maximise the motor re- sponses required Cortex controls patterns of movement not singu- lar muscular actions Neces- sary to return to normal developmental sequence for recovery	Diagonal and spiral pat- terns of active and pas- sive movement Quick stretch at end of range to promote con- traction following relax- ation in antagonists Maximal resistance is given by therapist to fa- cilitate maximal activity in the range of the re- quired movement. Voluntary contraction of the targeted muscle(s) Manual contact and therapist's tone of voice to encourage purposeful movement Isometric and iso- tonic contractions, trac- tion and approximation of joint surfaces to stim- ulate postural reflexes	Patterns of movement Stretch and postural re- flexes Manual pressure Isometric and isotonic contraction Approximation of joint surfaces Afferent input	Kabat 1953; Voss 1967
Brunnström (neurophysiological)	Uses primitive reflexes to initiate movement and encourages use of mass patterns in early stages of recovery Aims to encourage re- turn of voluntary move- ment through use of re- flex activity and sensory stimulation Assumes recovery pro- gresses from subcortical to cortical control of muscle function Stages of recovery: flac- cidity; elicit major syn- ergies at reflex level; es- tablish voluntary control of synergies; break away from flexor and exten- sor synergies by mixing components from antag- onist synergies; more dif- ficult movement combi-	Use tasks that patient can master or almost master. Sensory stimulation: from tonic neck or labyrinthine re- flexes, or from stroking, tapping muscles	Sensory cues Synergies	Brunnström 1956; Brunnström 1961; Brunnström 1970; Perry 1967; Sawner 1992

	nations mastered; indi- vidual joint movements become possible; volun- tary movement is elicited			
Bobath or neurodevelopmental ap- proach (NDT) (neurophysiological)	Aim to control afferent input and facilitate nor- mal postural reactions Aim to give patients the experience of nor- mal movement and affer- ent input while inhibit- ing abnormal movement and afferent input To improve quality of movement on affected side, so that the 2 sides work together harmo- niously Assumption that increased tone and increased reflex activity will emerge as a result of lack of inhibition from a damaged postural re- flex mechanism. Move- ment will be abnormal if comes from a back- ground of abnormal tone Tone can be influenced by altering position or movement of proximal joints of the body	pist, using direct han- dling of the body at key points such as head	Abnormal postural reflex activity/tone Postural control	Bobath 1959; Bobath 1966; Bobath 1970; Bobath 1978; Bobath 1990; Davies 1985; Davies 1990; Mayston 2000
Johnstone (neurophysiological)	To control spasticity by inhibiting abnormal pat- terns and using position- ing to influence tone Assumes that damaged postural reflex mecha-	Use of inflatable splints Emphasis on correct po- sition and use of splints Early stages: patient in side lying, with splint on affected arm	Muscle tone Air/pressure splints Positioning Reflex inhibition Tonic neck reflex Anti-gravity patterns	Johnstone 1980; Johnstone 1989

	nism can be controlled through positioning and splinting Based on hierarchical model that assumes re- covery is from proximal to distal Aim to achieve cen- tral stability, with gross motor performance, be- fore progressing to more skilled movements Inflatable air splints: ap- ply even, deep pressure to address sensory dys- function	Treatment progresses through hierarchy of ac- tivities, progressing from rolling through to crawl- ing Family involvement en- couraged		
Carr and Shepherd or motor learning or motor relearning or movement science (motor learning)	learn in the same way as healthy people. Assumes that motor con- trol of posture and move- ment are interrelated and that appropriate sensory input will help modulate the motor response to a task Patient is an active learner Uses biomechanical analysis of movement Training should be con- text-specific Essential for motor learning: elimination of unnecessary muscle ac-	 (1) Analysis of task (2) Practice of missing components (3) Practice of task (4) Transference of training Biomechanical analysis with movements compared to the normal Instruction, explanation and feedback are essential parts of training Training involves practice with guidance from therapist: guidance may be manual (but is used for support or demonstration, not for providing sensory input) Identifiable and specific goals Appropriate environment 	Motor control Motor relearning Feedback Practice Problem solving Training	Carr 1980; Carr 1982; Carr 1987a; Carr 1987b; Carr 1990; Carr 1998
Conductive education or Peto (motor learning)	Aims to teach pa- tient strategies for deal- ing with disabilities in order to encourage them to learn to live with or overcome disabilities Integrated approach em- phasising continuity and	Educational principles and repetition used as a method of rote learning Highly structured day Group work Task analysis Repe-	Education Rhythmical intention Intention Integrated system Group work Conductor Independence	Bower 1993; Cotton 1983; Kinsman 1988

Affolter (motor learning)	of learning Perception seen as hav- ing an essential role in the cycle of learning Incoming information is compared with past ex- perience ('assimilation'), which leads to anticipa- tory behaviour Assimilation and antici-	proach started from the- ory, rather than from clinical practice Starting at an elementary level, there will be no an- ticipation The patient starts to ini- tiate more steps There is increased antic- ipation of the steps to be taken	Complex human perfor-	Affolter 1980
Sensory integration or Ayres	Functional limitations compounded by sensory and percep-	Sensory feedback Repetition	Sensory and perceptual impairment Behavioural goals	Ayres 1972

(motor learning)	tual impairment Sensory feedback and repetition seen as impor- tant principles of motor	Feedback Repetition Adaptive response	
	learning		

The criteria listed in this Table are those used in previous versions of this review. These criteria are not used in this updated version of the review. (See Table 2 for the criteria used for classification of interventions within this updated review).

Table 2. Classification of categories and individual treatment components

Categories	Treatment component	Description of individual treatment component	
Assistive devices (AD)	Walking aids	Devices to assist walking, including sticks and frames	
	Orthoses for walking	Externally applied orthoses to assist walking, including AFO, knee braces	
	Resting splints	Externally applied orthoses to maintain or improve limb alignment	
Cardiopulmonary interventions (CI)	Aerobic/fitness/endurance training	Activities to improve cardiopulmonary fitness	
Functional task training (FTT)	ADL training	Practice of tasks relevant to daily life, includ- ing both part and whole task practice	
	Sitting &/or standing balance training	Various activities performed sitting &/or standing with the aim of improving the ability to balance safely and indepen- dently	
	Sit-to-stand practice	Practice of tasks aimed at improving ability to stand up and sit down safely and independently	
	Transfer practice	Practice of tasks aimed at improving ability to move from one position to another	
	Walking	Practice of tasks aimed at improving ambu- lation	
	Stair climbing	Practice of tasks aimed at ability to go up and down stairs	

	Upper limb function training	Practice of tasks aimed at improving the abil- ity to move and use the arm, such as reach, grasp, and hand-to-mouth ac- tivities
	Described as "MRP" (MRP - Motor Relearn- ing Programme)	Described as MRP
Modality (Mo)	Acupuncture	as an adjunct, delivered for either pain relief or movement therapy
	Physical agents (including hot, cold, TENS - Transcutaneous electrical nerve stimulation)	as an adjunct, delivered for either pain relief or movement therapy
Musculoskeletal intervention (active)	Muscle strengthening	Practice of activities to progressively increase the ability to generate muscle force, including using body weight and external resistance
	Active & active-assisted movement	Moving a limb through its range of move- ment, under the patient's active control with or without assistance
Musculoskeletal intervention (passive)	Increasing angle of upright sitting	a form of positioning, to promote early sit- ting
	Tilt table	To promote early lower limb loading
	Passive movement	Moving a limb through it's range of move- ment, whilst the patient is passive
	Body & limb positioning	placing a limb or body part in a supported position, to maintain optimal alignment
	Massage	Manipulation of soft tissue, using the hands or a tool designed for the purpose
Neurophysiological intervention	Hands on facilitation of ('normal') move- ment (Bobath)	Intervention which is described as facilitation of movement, referenced to Bobath or Davies
	Inhibition of abnormal muscle tone / nor- malising tone (Bobath)	Intervention which is described as inhibition of abnormal muscle tone or as normalising muscle tone, referenced to Bo- bath or Davies
	Described as "Bobath"	Described as Bobath

Table 2. Classification of categories and individual treatment components (Continued)

Table 2. Classification of categories and individual treatment components (Continued)

Trunk mobilisations / postural reactions (Bo- bath)	Intervention which is described as trunk mo- bilisations or postural reactions to perturbations, referenced to Bobath or Davies
Proprioceptive Neuromuscular facilitation (PNF - proprioceptive neuromuscular facili- tation)	Described as PNF
Sensorimotor facilitation	The use of excitatory techniques, such as brushing, striking, tapping, icing, to improve sensory awareness and promote muscle activity

AD: assistive devices; CPI: cardiopulmonary interventions; FTT: functional task training; MoD: Modality; Musc.(active): musculoskeletal intervention (passive); NP: neurophysiological intervention.

Study	Group	Categories (a	Categories (and treatment components)

Table 8. Study location and control intervention

Conti- nent / Control intervention	1	Australia & New Zealand	North America & Canda	South America	Asia (China)	Asia (other)	TOTAL
No treatment	5	0	3	1	44	1	54
Usual Care	6	1	4	0	5	1	17
Attention Control	1	6	2	0	1	0	10

Table 8. Study location and control intervention (Continued)

Active intervention	10	2	3	0	4	6	25
TOTAL	22	9	12	1	54	8	106

Table shows number of studies with different types of control group, in studies carried out in different continents. Two studies were each carried out in 2 continents; and 5 studies had two comparison interventions. Thus the 99 studies include a total of 106 control interventions on different continents.

WHAT'S NEW

Last assessed as up-to-date: 6 February 2014.

Date	Event	Description
15 November 2013	New citation required and conclusions have changed	A substantial amount of new information has been in- cluded in this review. The conclusions of the review have changed since the previous version; the compar- isons and the method of categorising interventions have also changed
15 November 2013	New search has been performed	Title changed from "Physiotherapy treatment approaches for the recovery of postural control and lower limb function" to "Physical rehabilitation approaches for the recovery of function and mobility following stroke". We have updated the searches to December 2012. We included 79 new studies in this version: the review now has 96 included studies involving 10,401 participants

HISTORY

Protocol first published: Issue 1, 2000

Review first published: Issue 2, 2003

Date	Event	Description
30 September 2008	Amended	Converted to new review format.
19 January 2006	New search has been performed	 2001 Version 4114 trials from electronic searching 167 abstracts screened 71 full papers assessed

(Continued)

 11 trials included (362 patients): Dean 1997; Dean 2000; Duncan 1998; Gelber 1995; Inaba 1973; Langhammer 2000; Pollock 1998; Richards 1993; Stern 1970; Wagenaar 1990; Wellmon 1997 Data for: four trials of neurophysiological versus other; four trials of motor learning versus other; four trials of mixed versus other; two comparisons of subgroups of the same approach. 2005 Update 8408 (4294 new) trials from electronic searching 266 (99 new) abstracts screened 185 (114 new) full papers assessed 20 (11 new) trials included (1087 patients; 809 new). New trials: Duncan 2003, Green 2002, Hesse 1998, Howe 2005, Lincoln 2003, McClellan 2004, Mudie 2002, Ozdemir 2002, Salbach 2004, Wade 1992, Wang 2005a Trials comparing subgroups of the same approach were excluded (excluded Inaba 1973 and Wagenaar 1990, which were included in original version) Data for: eight (four new) trials of neurophysiological (all Bobath) versus other;
 eight (four new) trials of motor learning versus other; nine (five new) trials of mixed versus other.

CONTRIBUTIONS OF AUTHORS

Alex Pollock (AP), for the 2007 and earlier versions: planned and co-ordinated all stages of the review; carried out searches, identified relevant studies and screened abstracts for relevant trials; co-ordinated and wrote the classification of rehabilitation approaches; wrote the 2007 amendment to the original protocol; classified the interventions administered in each trial; documented methodological quality of studies; contacted and communicated with trial authors; extracted data from included studies; planned the analyses and entered data into RevMan and wrote all drafts of the review. For this version: secured funding; planned and co-ordinated all stages of the review; screened abstracts; checked documented methodological quality of studies; planned analyses; checked data entry; carried out subgroup and sensitivity analyses; led stakeholder group meetings and wrote drafts of the review.

Pauline Campbell (PC), for this version: carried out searches, screened titles and abstracts; co-ordinated consensus decisions between review authors; entered descriptions of studies into RevMan; documented the methodological quality of studies; contacted and communicated with trial authors; extracted data from included studies and entered data into RevMan; created and entered data into tables summarising treatment components of included studies and contributed to writing and commented on draft versions of the written review.

Pei Ling Choo (PLC), for this version: screened abstracts in Chinese; translated necessary information for two review authors to reach consensus on inclusion of Chinese studies; translated written descriptions of interventions from Chinese into English; assessed methodological quality of Chinese studies; classified treatment components of all (Chinese and English) studies; contributed to stakeholder group meetings; contributed to conclusions drawn from the results and commented on draft versions of the written review.

Gill Baer (GB), for the 2007 and earlier versions: screened abstracts for relevant trials; contributed to the written criteria for classifying rehabilitation approaches; classified the interventions administered in each trial and discussed any discrepancies with AP to reach consensus; documented methodological quality of studies; extracted data from included trials and commented on draft versions of the written review. For this version: identified relevant studies for inclusion at full paper stage; discussed inclusion of studies at consensus meetings; contributed to stakeholder group meetings; contributed to conclusions drawn from the results and commented on draft versions of the written review.

Anne Forster (AF), for this version: contributed to the funding application that supported the stakeholder group and review update; contributed to stakeholder group meetings; provided methodological expertise in relation to identification of treatment components, including discussions with wider groups of physiotherapists and stroke survivors; contributed to conclusions drawn from the results and commented on draft versions of the written review.

Jacqui Morris (JM), for this version: contributed to the funding application that supported the stakeholder group and review update; contributed to stakeholder group meetings; contributed to conclusions drawn from the results and commented on draft versions of the written review.

Valerie Pomeroy (VP), for the 2007 and earlier versions: contributed to the formation of the protocol; screened abstracts for relevant trials for the first version of the review; contributed to the written criteria for classifying rehabilitation approaches and commented on draft versions of the written review. For this version: contributed to conclusions drawn from the results and commented on draft versions of the written review.

Peter Langhorne (PL), for the 2007 and earlier versions: provided substantial input to the formation of the protocol and provided methodological support at all stages of the review; discussed disagreements between independent review authors (AP and GB) regarding inclusion and methodological quality of trials; supervised data analysis and commented on draft versions of the written review. For this version: contributed to the conclusions drawn from the results and commented on draft versions of the written review.

DECLARATIONS OF INTEREST

Authors Alex Pollock and Gillian Baer carried out trials included in this review (Baer 2007; Pollock 1998).

DIFFERENCES BETWEEN PROTOCOL AND REVIEW

Title

For the protocol and for versions of the review published in 2007 and earlier, the title of this review was 'Physiotherapy treatment approaches for the recovery of postural control and lower limb function following stroke.' For the 2013 version of this review, the title was changed to 'Physical rehabilitation approaches for the recovery of function and mobility following stroke.' We made this change to reflect the more international perspective of this review update and the fact that 'physiotherapy' is not a universally adopted term, and to more accurately reflect the primary and secondary outcomes of the review.

Objectives

The objectives within the protocol and versions published in 2007 and earlier were focused on "the recovery of postural control and lower limb function." In this update, this has been amended to read "the recovery of function and mobility." This difference relates only to the terminology used, not to the selection of primary or secondary outcomes within the review.

The reason for originally highlighting the focus on postural control and lower limb function was specifically to highlight that this review excluded studies related to upper limb interventions and recovery only. However, feedback from stakeholder group members indicated that the original objectives were perceived to be misleading, as they did not incorporate the primary outcomes, which were measures of disability, and prestated relevant measures of disability such as (1) independence in ADL scales*; or (2) motor function scales.* The stakeholder group reached consensus that the phrase "function and mobility" was more correct and appropriate to reflect the focus of this review within the stated objective (and title).

The original protocol stated a number of hypotheses. These have been removed from this update. (Original text: "Hypotheses to be tested: (1) physiotherapy treatment based on neurophysiological principles results in better recovery of postural control and lower limb function than treatment based on motor learning principles, orthopaedic principles results in better recovery of postural control and lower limb stroke; and (2) physiotherapy treatment based on motor learning principles results in better recovery of postural control and lower limb function than treatment based on orthopaedic principles, or on a mixture of treatment principles in patients with stroke.")

* Names of measures of disability

In the protocol and in previous versions of the review, the primary outcome of measures of disability was divided into two prestated subcategories of:

1. global dependency scales (including Barthel Activities of Daily Living Index, Functional Independence Measure (FIM),

Modified Rankin Scale, Katz Index of Activities of Daily Living, Rehabilitation Activities Profile); and

2. functional independence scales (including Motor Assessment Scale (MAS), Fugl-Meyer Assessment (lower limb section); Rivermead Mobility Index; Rivermead Motor Assessment).

For this update, we changed the names of each of these two subcategories (but not the content) because we considered that the original names were now potentially confusing, as other terms are more usually used in published research. The replacement names are (1) independence in ADL and (2) motor function.

Outcomes

The protocol defined secondary outcomes as measures of motor impairment, classifying them as measures of:

- 1. postural control and balance;
- 2. voluntary movement (including movement associated with gait);
- 3. tone or spasticity;
- 4. range of movement; and
- 5. strength.

The protocol also identified participation (handicap or quality of life) as an outcome of relevance to this review.

For the 2007 version of the review, the review authors documented and extracted descriptions and data from any outcomes falling into the groupings stated in the protocol. Based on the prestated groups of relevant outcomes and the availability of data from specific measures in the included trials, we discussed and reached consensus on which outcome measures should be included in the analysis. For this 2013 version of the review, the secondary outcomes remained the same as the outcomes analysed for the 2007 version (i.e. secondary outcomes).

- 1. Balance (Berg Balance Scale).
- 2. Gait velocity.
- 3. Length of stay.

In the protocol and in previous versions of this review, we carried out analysis only on outcomes reported immediately after the end of the intervention. In this 2013 version, we have carried out analyses on both outcomes reported immediately after the end of the intervention and on follow-up outcomes.

INDEX TERMS

Medical Subject Headings (MeSH)

*Posture; Activities of Daily Living; Biofeedback, Psychology [*methods]; Leg [physiology]; Motor Skills; Physical Therapy Modalities; Proprioception [physiology]; Randomized Controlled Trials as Topic; Recovery of Function; Stroke [*rehabilitation]
